DOTANG TO SERVE

WASHINGTON GOVERNMENT PRINTING OFFICE 1917 U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

Weather Bureau—C. F. Marvin, Chief.
Bureau of Animal Industry—A. D. Melvin, Chief.
Bureau of Plant Industry—W. A. Taylor, Chief.
Forest Service—H. S. Graves, Forester.
Bureau of Soils—Milton Whitney, Chief.
Bureau of Chemistry—C. L. Alsberg, Chief.
Bureau of Crop Estimates—L. M. Estabrook, Statistician.
Bureau of Entomology—L. O. Howard, Entomologist.
Bureau of Biological Survey—E. W. Nelson, Chief.
Office of Public Roads and Rural Engineering—L. W. Page, Director.
Office of Markets and Rural Organization—C. J. Brand, Chief.

STATES RELATIONS SERVICE—A. C. True, Director.
OFFICE OF EXPERIMENT STATIONS—E. W. Allen, Chief.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA-

College Station: Auburn; J. F. Duggar.¹
Canebrake Station: Uniontown; L. H. Moore.¹
Tuskegee Station: Tuskegee Institute; G. W. Carver.¹

ALASKA—Sitka: C. C. Georgeson.²
ARIZONA—Tucson: R. H. Forbes.¹
ARKANSAS—Fayetteville: M. Nelson.¹
CALIFORNIA—Berkeley: T. F. Hunt.¹
COLORADO—Fort Collins: C. P. Gillette.¹
CONNECTICUT—

State Station: New Haven; Storrs Station: Storrs;

DELAWARE—Newark: H. Hayward.
FLORIDA—Gainesville: P. H. Rolfs.
GEORGIA—Experiment: J. D. Price.
GUAM—Island of Guam: C. W. Edwards.
HAWAI—

Federal Station: Honolulu; J. M. Westgate.² Sugar Planters' Station: Honolulu; H. P. Agee.¹

IDAHO—Moscow: J. S. Jones.¹
ILLINOIS—Urbana: E. Davenport.¹
INDIANA—La Fayette: A. Goss.¹
IOWA—Ames: C. F. Curtiss.¹
KANSAS—Manhattan: W. M. Jardine.¹
KENTUCKY—Lexington: A. M. Peter.⁴
LOUISIANA—

State Station: Baton Rouge; Sugar Station: Audubon Park, New Orleans;

North La. Station: Calhoun; MAINE-Orono: C. D. Woods. 1

MARYLAND—College Park: H. J. Patterson. 1
MASSACHUSETTS—Amherst: W. P. Brooks. 1
MICHIGAN—East Lansing: R. S. Shaw. 1
MINNESOTA—University Farm, St. Paul: A. F. Woods. 1
MISSISSIPPI—Agricultural College: E. R. Lloyd. 1

MISSOURI— College Station: Columbia; F. B. Mumford.¹

Fruit Station: Mountain Grove; Paul Evans. 1

Director. 2 Agronomist in charge. 3 Anim

Montana—Bozeman: F. B. Linfield.¹
Nebraska—Lincoln: E. A. Burnett.¹
Nevada—Reno: S. B. Doten.¹
New Hampshire—Dutham: J. C. Kendall.¹
New Jersey—New Brunswick: J. G. Lipman.¹
New Mexico—State College: Fabian Garcia.¹

NEW YORK-

State Station: Geneva; W. H. Jordan. Cornell Station: Ithaca; A. R. Mann.

NORTH CAROLINA-

College Station: West Raleigh; B. W. Kilgore. 1
State Station: Raleigh;

NORTH DAKOTA—Agricultural College: T. P. Cooper. 1
OHIO—Wooster: C. E. Thorne. 1
OKLAHOMA—Stillwater: W. L. Carlyle. 1
OREGON—Corvallis: A. B. Cordley. 1

PENNSYLVANIA-

State College: R. L. Watts.¹
State College: Institute of Animal Nutrition,
H. P. Armsby.¹

PORTO RICO-

Federal Station: Mayaguez; D. W. May.²
Insular Station: Rio Piedras; W. V. Tower.¹

RHODE ISLAND—Kingston: B. L. Hartwell.¹
SOUTH CAROLINA—Clemson College: H. W. Barre.¹
SOUTH DAKOTA—Brookings: J. W. Wilson.¹
TENNESSEE—Knozville: H. A. Morgan.¹
TEXAS—College Station: B. Youngblood.¹
UTAH—Logan: F. S. Harris.¹

VERMONT—Burlington: J. L. Hills.1

VIRGINIA-

Blacksburg: A. W. Drinkard, jr. 1 Norfolk: Truck Station; T. C. Johnson. 1

Washington—Pullman: I. D. Cardiff.¹
West Virginia—Morgantown: J. L. Coulter.¹
Wisconsin—Madison: H. L. Russell.¹
Wyoming—Laramie: H. G. Knight.¹

Agronomist in charge. Animal husbandman in charge. Acting director.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., Chief, Office of Experiment Stations. Assistant Editor: H. L. Knight.

CONTENTS OF VOLUME 35, NO. 1.

Editorial notes:	Page.
Impressions of the stations in the Southwest	1
Recent work in agricultural science.	8
Notes.	96
SUBJECT LIST OF ABSTRACTS.	
AGRICULTURAL CHEMISTRY—AGROTECHNY.	
Practical organic and biochemistry, Plimmer	8
The world of neglected dimensions, Ostwald.	8
Reports on progress of chemistry for 1913-14, edited by Cain and Greenaway	0
Reports on progress of Chemistry for 1915-14, edited by Cam and Greenaway	0
Report of the agricultural chemist, Brunnich	8 8 8 8
On the isolation and properties of tethelin, Robertson	9
A new method for the preparation of the plant globulins, Reeves	
Notes on some fatty and essential oils, Higuchi.	9
The composition and analysis of edible oils and fats, Bolton and Revis	9
Tobacco seed oil, Cohen	9
Stearins in fats and behavior during hydrogenation, Marcusson and Meyerheim.	9 9
Some important fermentations in silage, Hunter and Bushnell	
On the urease of the soy bean and its "coenzym," Onodera	10
The effects of various substances upon the urease of soy bean, Onodera	10
Factors influencing catalase in milk, Höyberg	10
Notes on the catalase reaction of milk, Taylor	10
The persistence of hydrogen peroxid in milk, Hinks	11
Commercial and industrial analysis (organic), Halphen and Quillard	11
, , , , , , , , , , , , , , , , , , , ,	

	Page.
Boiling and condensing points of alcohol-water mixtures, Evans	11
The electrolytic determination of iodin present in organic matter, Krauss	îî
A proposed new method for citrate-insoluble phosphoric acid, Hunt	12
Citric-acid-soluble phosphoric acid in slag, Celichowski and Pilz	12
The determination of potassium in fertilizers, Pilz	12
Note on the estimation of fat in food for infants, Chapman	12
Analysis of maple products.—VI, Test for purity of maple sirup, Snell et al	12
The determination of cholesterol in blood, Bloor	13
The determination of cholesterol in blood, Bloor	13
A method for the determination of alcohol in the presence of phenol, Ehrlich	13
Rapid pycnometric method for "gravity solids" in cane-sugar factories, Walker.	14
Theories on formation of molasses from standpoint of phases, van den Linden	14
Proposed method for profitable utilization of waste sulphite liquor, Tartar	14
Fruit preserving: Canning, bottling, jam-making, and candying peel, Allen	.14
METEOROLOGY.	
Climatic variations and economic cycles, Huntington	7.4
The money value of rainfall in the United States, Cragoe	14 14
Protection from damage by frost, Reed	15
Relation of the soil to the meteorological factors, Loske.	15
Aridity and humidity maps of the United States, Jefferson.	15
Agricultural meteorology in Canada, Mills	15
[Report of the] committee for the investigation of atmospheric pollution	15
SOILS—FERTILIZERS.	
A guide to the mineralogical analysis of soil, Seemann	16
The data of geochemistry, Clarke	16
The plasticity of clay and its relation to mode of origin, Davis	16
On osmosis in soils, Lynde and Dupré	16
Salts, soil colloids, and soils, Sharp	$\frac{16}{17}$
Soil survey of Mississippi County, Arkansas, Hall et al.	17
Soil survey of Webster Parish, Louisiana, Meyer et al.	17
Soil survey of Montgomery County, Maryland, Carter, jr., and Hull	18
Soil survey of Clinton County, New York, Maxon and Cone	18
Soil survey of Trumbull County, Ohio, Coffey et al	18
Soil survey of Raleigh County, West Virginia, Latimer	18
Soil survey of Fond du Lac County, Wisconsin, Whitson et al	19
Soil survey of Juneau County, Wisconsin, Whitson et al	19
Soil survey of Kewaunee County, Wisconsin, Whitson et al	19
Soil survey of La Crosse County, Wisconsin, Whitson et al	19
The chemical composition of virgin and cropped Indiana soils, Conner	19
Plant food in Aroostook soils, Woods	19
A peculiar clay from near the City of Mexico, Hilgard	19
Analyses of Queensland soils, Brunnich	20
Chemical composition of certain vineyard soils, Perold and Crawford	20
Relation of carbon bisulphid to soil organisms and plant growth, Fred	20
The effect of heat upon soil fertility, Owen. The influence of nitrification upon soil fertility, Owen.	$\frac{20}{21}$
Physical-chemical studies of soil.—III, Pratolongo	21
Effect of Vanillin as a soil constituent Skinner	21
Experiments on lime determination in agricultural soil, Bandi.	21
Plant foods for crops in 1916, Van Slyke	21
Experiments with fertilizers, Bear	22
Culture experiments with nitrogenous fertilizers, von Reibnitz	22
Granulated calcium cyanamid (Norwegian lime nitrogen), Hals	22
Acid soils and the effect of fertilizers upon them, Conner	22
Phosphatic fertilizers and the root system of beets, Sazanov	23
Phosphate rock, Waggaman	23
Potassium salts, Dolbear	23
Investigation of sources of potash in Texas, Phillips	23
Potassium salts in Catalonia, Rubio and Marin.	24
German and other sources of potash supply, MacDowell.	24
Sodium and sodium salts, Salisbury, jr	24

	90
T' A DT AT TILL I A A	Page.
Limestone: North Island analyses, Aston	24
A waste lime product, Thorne The use of peat in commercial fertilizer, Wildeman	24
The use of peat in commercial fertilizer Wildeman	24
Zao do or powers commercial returner, waterman	2'1
AGRICULTURAL BOTANY.	
Relation of green manures to the failure of certain seedlings, Fred	24
Activities of the micro-organisms of the soil	25
Activities of the micro-organisms of the soil. Fission fungi which decompose urea and form nitrates, Düggeli.	
resion rangi which decompose area and form intrates, Duggeri	25
Enzym action in the marine algæ, Davis	25
On the action of pectase, Ball. Osmotic pressures in plants.—IV, Dixon and Atkins.	25
Osmotic pressures in plants.—IV. Dixon and Atkins	25
Osmotic pressures in plants.—V, Dixon and Atkins. Some researches in experimental morphology.—I, Doyle	26

EXPERIMENT STATION RECORD.

Vol. XXXV.

July, 1916.

No. 1.

Some of our strongest impressions are gathered from seeing with our own eyes and experiencing by contact the things going on about us. It is so with the progress of the experiment stations. We may read about it in their reports and hear about it at meetings, but only through coming into contact with these institutions in their local environment can an adequate idea be had of their scope, variety, and vital place in the community, as well as the actual conditions under which they are working.

Such an opportunity for study is given by the annual visitation of the stations, made by representatives of this Office. And as several years usually elapse between the visits of the same individual, the chance is offered for measuring the growth and comparing the general situation. Taking account of any obstacles in the local situation as well as of the favorable conditions, the sympathetic if critical examination on such occasions seeks out the good quite as much as the weak, and in this attitude endeavors to gain a true perspective. It is a most interesting and stimulating experience—more so as the development goes on. In no other way can a fair understanding and a just appreciation of the stations be acquired.

A recent tour of a section of the South and West has given opportunity to come again into intimate contact and association with the stations in that region, and to see them at work in their own particular fields. The trip suggests some thoughts and impressions which, while not necessarily confined to that section, apply particularly to the stations there. Although they naturally present many and often wide differences, taken as a whole they are typical of the progress and the spirit of the present stage.

No one could pretend to study the work of an experiment station in a visit of two or three days, but by close, appreciative attention he may gain a knowledge of the men comprising the force, get an insight into their work, catch something of the spirit and atmosphere which dominates the institution, and gather an impression of the general situation. The latter relates to the conditions without as well as within the institution—the general attitude toward the station and its workers on the part of the public, the governing board, and the administrative officers. It reflects the encouragement and opportunity given the station, and the feeling as to the success and effectiveness of the work as a whole.

Right conditions are just as essential to success as the right kind of men, and these two essential elements can not be separated without influencing the general effectiveness. Favorable conditions are not alone a matter of funds or size of institution, or geography, or equipment, or even of being let alone. They are a matter of spirit, of leadership, of sympathetic encouragement and protection.

In these respects the situation has steadily improved and in general is most commendable—better in some places than in others, of course, but such everywhere as to make enthusiastic, ambitious workers, with confidence and pride in their station. Despite one or two disquieting evidences that tenure is not yet wholly a matter of merit, there was uniform evidence of a broader and more appreciative view and a better understanding of the requirements of station work. None of the stations visited have stood still; most of them have shown such distinct advancement as to make them unquestionably stronger, more influential, and in better condition than they have ever been before. Including as it does some of the newer country where development has been more tardy, the situation is most gratifying.

The credit for this progress rests back in large measure upon the personnel of the stations, the respect and support they have been able to command, the opportunity and protection accorded them. The men make the station, given the opportunity, and a station can not rise above the level they represent, no matter how generous the support. It is strange that this is not fully realized, for failure to appreciate it results in false economy.

No one can come into personal contact with the station workers on the field of their activity without being impressed with their zeal and industry. They are an unusually busy group of men, keen and alert, and with a zealous interest in the problems of the region which is blind to personal hardship or self-sacrifice. There is something remarkably fine in the spirit of service, of accomplishment, which ties these men to their field, particularly in the newer country where the appeal seems especially strong. It becomes a devotion; a man's life and personality seem centered in the new country and the young institution, and the advancement of these seems almost to be a personal aspiration with him.

The position of such men has been well stated by President Wilson, in a recent address in which he characterized the motives of men engaged in scientific work. He said: "There is something very intensely appealing to the imagination in the intellectual ardor which

men bestow upon scientific inquiry. No social advantage can be gained by it. No pecuniary advantage can be gained by it. In most cases no personal distinction can be gained by it. It is one of the few pursuits in life which gets all its momentum from pure intellectual ardor, from a love of finding out what the truth is, regardless of all human circumstances—as if the mind wished to put itself into intimate communication with the mind of the Almighty itself. There is something in scientific inquiry which is eminently spiritual in its nature. It is the spirit of man wishing to square himself accurately with his environment, not only, but also wishing to get at the intimate interpretations of his relationship to his environment. . . .

"So when I stand in the presence of scientific men I seem to stand in the presence of those who are given the privilege, the singular privilege, the almost contradictory privilege, of following a vision of the mind with open, physical eyes; making real the things that have been conjectural; making substantial the things that have been intangible."

intangible.

This is singularly applicable to those engaged in the various forms of agricultural work. Nowhere does the vision seem to be more aluring or the opportunity greater to "make real the things that have been conjectural" and to put this knowledge into tangible, living form. The possibilities and the desire for help stimulate the responsive workers to unusual activity and effort. Everywhere these men are found to be carrying a heavy load of teaching in the college, with increasing requirements from regular and graduate students, and subject to almost constant appeals for assistance of a kind which they can not turn over to the extension departments. Despite the more general differentiation and specialization of duties, the station men especially often find themselves loaded with more work than they can prosecute as they would like to, and are led by their enthusiasm to work under unusually high pressure. When a man carrying sixteen hours a week of teaching throughout the year voluntarily conducts an active line of station investigation, often involving personal hardship in the making of trips, no doubt can remain of his zeal and his determination not to be deterred by circumstances.

One wonders whether there is another branch of investigation where the problems press so hard and the eagerness for help makes so strong an appeal to the very best there is in men. The field is so inspiring and stimulating, and gives such a vital opportunity for direct service that the men need often to be guarded against overwork or the tendency to lay out more than can be wisely undertaken. In such cases the workers need protection from themselves and their friends, for they can not be constantly turned from their investigations, and they must recognize the limitations to their time and strength.

The station workers sometimes need protection in another direction, namely, against unfair critics and unknowing or self-seeking factions. These are far less common than formerly but they still have to be reckoned with. Such a hostile attitude is sometimes directed against the station as an organization but more often against an individual member, especially the director. Upon these administrative officers the burden rests heavily. A variety of responsibilities are entrusted to them. The various sections and interests of a large State have to be considered, and often are in competition. Suggestion and argument sometimes proceed to the point of attempted dictation. Activity in the latter direction by organizations in a number of States constitutes a new menace. In such cases the governing board can prove a tower of strength to the administrative officers and can protect the station from being stampeded or subjected to domination.

Station directors, being human, make mistakes, but usually their errors are errors of judgment rather than violations of principle. They are honest, and they have the success of their work at stake. Their interest in the welfare of the institution usually far transcends that of private individuals or organizations who are attempting to rule and threatening as an alternative to ruin. To cast lightly aside a director or take away his power because of attack upon him is to deprive the station of the main support it has a right to expect from the governing board, and to encourage a condition which will make successful administration a difficult matter.

Fortunately, the position of director has been almost entirely divorced from politics and from personal influence, and has usually been based on merit and ability alone. The good a successful director does and the results he accomplishes far transcend his occasional mistakes, and his case deserves to be considered squarely on its merits, having in mind his record for constructive work and his value to the State.

The increase in physical equipment and in financial support of the stations in this western section makes a deep impression on the casual visitor. The crude conditions of a few years ago have given way to substantial provision in accord with the present needs. It is an evidence of the acceptance of the station as a necessary agency for safe progress, and of a willingness to meet its real requirements. On every hand there are signs of this, and of the fact that the people are not only in a receptive mood and ready to follow the advice of the stations, but that they are leaning upon them for guidance—in the development of such humble branches as goat farming as well as in matters pertaining to the highly developed citrus industry.

We find, for example, in Texas a system of eleven state stations, to study the problems of particular regions and special industries or

types of farming, closely correlated with a strong central station at the college. This system is supported by a lump sum appropriation of \$135,000 annually, together with proceeds from sales amounting to upwards of ten thousand more. This shows a liberality and confidence quite out of harmony with the present tendency in some States to tie up the appropriations to specified expenditures and lines of work, and to take away from the station any incidental revenue derived from sales or fees.

The New Mexico Station is encouraged and heartened by its first state appropriation for support, which although small is of material assistance. One of its special features of equipment is a spacious outdoor laboratory for studying the duty of water in agriculture, hardly equaled anywhere. The facilities offered in Arizona are excellent and would be a surprise to one visiting the station for the first time. Among notable additions are a splendid new agricultural building, a pride to any State and an ornament to any campus, and a new farm of 160 acres to better meet the needs of field work in the Salt River Valley.

We have learned to expect large things of California, but the extent to which it is meeting the needs of its varied agriculture, from the tropical region of the Imperial Valley to the northernmost part of the State, leaves no doubt of the place the station work has made for itself in that State. A citrus station is being developed in the southern end which will be unequaled in the world, with opportunity for investigation and advanced study over the whole range of subtropical agriculture. The new tract of 475 acres at Riverside, recently purchased for this station at a cost of \$55,000, is now being made ready, and the plans have been approved for buildings to be erected with a \$125,000 appropriation. At Berkeley a \$360,000 addition to the large agricultural building erected a few years ago is planned for, to relieve the crowded condition of nearly all the agricultural departments.

Elsewhere the progress is hardly less noticeable, if not on as large a scale. Missouri and Kansas some time ago provided their complement of buildings for agriculture, and are constantly increasing the special facilities in the way of equipment and apparatus. Minor changes are also developing in other States to meet the needs of particular lines of investigation, such as the veterinary work in Nevada, the poultry work in Utah, etc. Few stations, irrespective of size, have more adequate equipment for investigation in chemistry and meteorology than in Nevada, and the special provision made in Missouri and Kansas for studies in the use of feed by growing animals is widely known.

It is worthy of note that not a single station in the region visited fails to receive some state appropriation for its maintenance, and frequently the amount is very large. This, it is to be remembered, is in a relatively new section in much of which cultivated agriculture is only partially developed as yet, and where only a few years ago the need for the work of an experiment station was but slightly felt. The eight stations in the section in question are this year devoting a total of considerably more than three-quarters of a million dollars to their work, aside from appropriations for new building—a worthy example for some of the States farther East.

It is highly gratifying, furthermore, to find the names of the pioneers in agricultural service immortalized in the buildings crected for agriculture, often as stately and imposing as any on the campus, and worthy memorials to those who laid the foundations for the present great development. It shows that at heart the people are grateful. Confidence in this fact is surely one of the rewards of

service, even if evidence of it is sometimes delayed.

But more remarkable even than physical equipment or than the generous financial support is the impression which the work itself makes upon the visitor in going from station to station. The extent of it and the great range and variety of it are well-nigh bewildering—from such unusual subjects as the ostrich and the date and the cactus in Arizona, the citrus, avocado, and wine and raisin grapes in California, the range problem in Nevada, the alkali and irrigation studies of other sections, and the problems of dry farming, to the more familiar ones of grain and stock farming in the humid sections.

Many of the broad general subjects are of course similar all over the country, and fall into certain rather definite classes, but the infinite variations given to common topics in different places by reason of the special conditions of the sections illustrate, as almost nothing else does, the enormous variation in environment and the necessarily local character of many lines of inquiry. It shows that natural laws must be very broad to cover such a range of differences, and that facts and principles assumed to have been established are more restricted than supposed and often require local adaptation.

These things make the work not only varied but highly specialized. Fighting drought in one section, overcoming it with irrigation in others, and avoiding the effects of too much water elsewhere—each brings its own special group of problems to tax the knowledge and the ingenuity of the most versatile investigator. The difference in the behavior of the same kind of soil in California and in Kansas, and the variation in the life history of insects and organisms causing diseases in sections having different climate and season, contribute to the almost endless variation in plan and method as well

as in results. A scale in southern California apparently withstands heavier doses of poisonous gas than the same species elsewhere, a type of cultivation is found adapted in one section and inadvisable in another, peculiar effects of soil on the crop are unmistakable in some places and absent in others—no wonder there are conflicting reports, differences of opinion, and controversy. The accumulation of these facts teaches both caution in too wide application of the findings and tolerance of the views and results of others. Both parties may be right when the whole truth is known.

Whether the work deals with practical economic experiments in the culture of plants and the feeding of animals, the study of the principles of breeding them, the activities of the lesser forms of life that inhabit the soil, or the ravages of an insect or a plant disease, the final aim is control—dominion over the soil, the growing things, the elements; and where control and dominance are not feasible, the effort is no less direct to avoid or overcome the obstacles by adaptation or by finding some means of getting around them.

Everywhere the aim is to understand, to dominate and control through knowledge, to make intelligence take the place of blind force in fighting against the effects of adverse conditions and circumstances. And above all, to replace tradition with reliable information, and to establish in these early and prosperous days a basis of knowledge and intelligence which will prevent the coming of those hard conditions which result from worn-out soil and abusive practice.

43795°-No. 1-16-2

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Practical organic and biochemistry, R. H. A. PLIMMER (London and New York: Longmans, Green & Co., 1915, pp. XII+635, pl. 1, figs. 86).—This is a practical laboratory guide of organic chemistry in its relation to biochemistry. The scope of the volume has been extended over that of the author's earlier work, new sections on organic chemistry and organic substances found in plants having been added.

A list of standard and special reagents is appended.

The world of neglected dimensions, W. Ostwald (Die Welt der Vernachlüssigten Dimensionen. Dresden: Theodor Steinkopff, 1915, pp. X+219, pls. 6, fgs. 33).—This volume is the outcome of a series of lectures on colloid chemistry delivered during the winter of 1913–14 in the United States and Canada. The subjects discussed are (1) the fundamental phenomena of the colloid condition, colloids as disperse systems, and the methods of preparing colloidal solutions; (2) colloidal systems; (3) changes in colloid condition; (4) the scientific application of colloid chemistry; and (5) the technical and practical application of colloid chemistry. An appendix and a complete subject index are included.

Annual reports on the progress of chemistry for 1913-14, edited by J. C. Cain and A. J. Greenaway (Ann. Rpts. Prog. Chem. [London], 10 (1913), pp. IX+300, fig. 1; 11 (1914), pp. VIII+303, figs. 9).—These reports deal with the progress in general, physical, inorganic, organic, analytical, physiological, agricultural, and mineralogical chemistry, vegetable physiology, and radioactivity.

Report of the agricultural chemist, J. C. Brunnich (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1914-15, pp. 30-61).—This report contains a general review of the routine and investigational work carried on during the year 1914-15.

The results of the soil, water, seed, wheat, and flour analyses are recorded in tabular form, those of soils being also noted on page 20 of this issue.

On the isolation and properties of tethelin, the growth-controlling principle of the anterior lobe of the pituitary body, T. B. ROBERTSON (Jour. Biol. Chem., 24 (1916), No. 3, pp. 409-421, pl. 1).—The substance which appears to be the growth-controlling principle in the anterior lobe of the pituitary body was isolated by extraction with boiling alcohol, concentrating under reduced pressure to incipient separation of solid material, and then precipitating by anhydrous ether. The precipitate thus formed was washed several times with a mixture of absolute alcohol and anhydrous ether and finally dried over sulphuric acid at a temperature of about 30 to 35° C.

The material is soluble in water, ethyl alcohol, ethyl ether, chloroform, and carbon tetrachlorid, but insoluble in an alcohol-ether mixture (1:1.5). It contains 1.4 per cent of phosphorus, and 2.58 per cent of nitrogen as determined by the Kjeldahl-Gunning-Arnold method. The P:N ratio is thus approximately 1:4, two nitrogen atoms of which are present as amino groups and a third as an

imino group, which on hydrolysis with barium hydroxid is converted to an amino group, as shown by an increase in the amino nitrogen content. From the products produced by hydrolysis with barium hydroxid several fractions were isolated, from one of which *d-l*-inosite was obtained.

In aqueous solution the substance does not yield the biuret reaction or reduce Fehling's solution. Qualitative tests indicate the presence of an iminazolyl group, and in this respect it seems to be related to the physiologically active principles of the posterior lobe of the pituitary, but it does not possess the characteristic properties of these substances, viz, the production of a rise in the blood pressure, stimulation of smooth muscles, and diuresis.

A new method for the preparation of the plant globulins, G. Reeves (Biochem. Jour., 9 (1915), No. 4, pp. 508-510).—The author describes a new procedure in which the proteins are obtained by extraction with a half-normal solution of sodium benzoate and precipitated from this extract by dilution with water. The amorphous material thus obtained can be obtained in the crystalline form in the usual manner of recrystallization from salt solution. Edestin from hemp seed, excelsin from the Brazil nut, and a mixture of legumin and vicillin from horse beans were thus prepared. Sodium salicylate was also tried as a solvent but was found to be unsuitable.

Notes on some fatty and essential oils, S. Higuchi (Extracts from Bul. Forest Expt. Sta., Tokyo, 1915, pp. 81–88).—The author reports the physical and chemical constants of various oils obtained from seeds and woods indigenous to Japan. The value and use of the various oils are indicated.

Recent advances relating to the composition and analysis of edible oils and fats, E. R. Bolton and C. Revis (Analyst, 40 (1915), No. 477, pp. 494-503).—This communication reviews in general the advances made in the subject of edible oils and fats during the past few years. The original references to the work are cited and briefly discussed.

Tobacco seed oil, N. H. COHEN (Indische Mercuur, 38 (1915), No. 43, pp. 884, 885; abs. in Jour. Soc. Chem. Indus., 35 (1916), No. 2, p. 126).—The oil obtained from the tobacco seed was found to be a rapid-drying oil and an excellent substitute for linseed oil. About 14.4 per cent of oil was obtained from the seed. The press cake was found to contain about 0.8 per cent of potassium, 1.15 per cent of phosphoric acid, and 4.2 per cent of nitrogen, as compared with 2.06 per cent of potassium, 1.5 per cent of phosphoric acid, and 4.2 per cent of nitrogen in the seeds.

Stearins occurring in fats and their behavior during hydrogenation, J. Marcusson and G. Meyerheim (*Mitt. K. Materialprüfungsamt Gross-Lichterfelde West*, 33 (1915), No. 3-4, pp. 221-226).—Experimental data demonstrating that during the hydrogenation of fats the stearins are not attacked or changed in any way are submitted. These results are in accord with those reported by Bömer (E. S. R., 28, p. 616).

Some important fermentations in silage, O. W. Hunter and L. D. Bushnell (Kansas Sta. Tech. Bul. 2 (1916), pp. 5-32).—This bulletin reports the results of a detailed study of the ripening changes occurring in silage. The results of the quantitative estimation of the total number of organisms in 1 cc. of a physiological salt solution extract and of the number of liquefiers, acid producers, Bulgarian group, yeasts, and colon group in Kafir corn, cane-fodder, and alfalfa silage are reported in tabular form. Chemical analyses relative to the moisture, total acidity, total volatile acidity, and total nonvolatile acidity, together with the surface and center temperatures of the silo, are also reported.

The effect of antiseptics on silage fermentation was also studied. Antiseptics were found to inhibit markedly the growth of the principal types of the microorganisms and consequently cause a marked decrease in the final total acidity.

It is indicated that in general the greater part of silage fermentation is due to the activity of micro-organisms consisting of four prominent groups, (1) the acid group, (2) the colon group, (3) yeasts, and (4) a miscellaneous type. The most important fermentation is that of acid production which is largely due to a group of organisms belonging to the Bulgarian group.

The morphology and the cultural and biochemical features of the Bulgarian group organisms are described in detail.

On the urease of the soy bean and its "coenzym," N. Onodera (Biochem. Jour., 9 (1915), No. 4, pp. 575-590).—It has been shown that "the urease of soy bean loses its activity on dialysis. The lost activity is restored by the addition of a small amount of fresh urease. This indicates that the fresh urease contains coenzym. The coenzym could not be separated, accordingly its nature is not yet known. It is very likely that the coenzym is a system consisting of two groups of components, one of which is dialyzable and the other undialyzable. The dialyzable component undergoes some irreversible change during dialysis.

"The coenzym consists of two parts, fixed and free. Heating and dialysis destroy the free coenzym first, then the fixed coenzym. The last portion of the fixed coenzym is found in the precipitate produced by dialysis, resisting the influence of heating and dialysis tenaciously. The inhibitory effects of heat, acid, and alkali are exerted upon the coenzym, but not upon the urease proper. In germination urease accumulates in the germs of the soy beans in large proportion, but free coenzym is absent. Although ox serum has an accelerating power, it contains no substance which can be compared with the coenzym."

On the effects of various substances (electrolytes, nonelectrolytes, alkaloids, etc.) upon the urease of soy bean, N. Onodera (Biochem. Jour., 9 (1915), No. 4, pp. 544-574, figs. 2).—The experimental data demonstrate that in the inhibitory effects of inorganic and organic acids on urease the hydrogen ion concentration plays a very important rôle, but does not coincide with this in the inhibitory effects of caustic soda and ammonia. The inhibitory effect of soda can be ascribed to the hydroxyl ion concentration, but ammonia has some further action. Methyl, ethyl, and propyl alcohol in 1-molar solutions and amyl alcohol in $\frac{1}{40}$ -molar solution accelerate the urease action, but stronger solutions retard the action. Aldehyde inhibits urease notably. The effect of neutral salts is due to their metallic bases. Tenth-normal solutions retard urease action because metallic bases displaced by the ammonia produce a greater hydroxyl ion concentration than the equivalent of ammonia. Alkaloid salts accelerate the action in the the first stage of hydrolysis. The bases, however, markedly inhibit the action.

Factors influencing catalase in milk, H. M. HÖYBERG (Ztschr. Fleisch. u. Milchhyg., 26 (1915), Nos. 5, pp. 70–74; 6, pp. 85–88; 26 (1916), No. 7, pp. 104–106).—The author concludes that the catalase activity of milk and serum is dependent on the protein, probably the albumin. Serum and milk can possess catalase properties in the absence of bacteria, cell elements, and fibrin. The catalase activity did not change in milk which has stood for 10 hours at 15° C. (59° F.), and in some cases an increase was evident. The activity was increased in many cases by heating to 45°, and at 68° the catalase is destroyed. Changes in the reaction of the milk do not affect the catalase, which is apparently contrary to the enzym theory of action.

Notes on the catalase reaction of milk, H. B. TAYLOR (Jour. and Proc. Roy. Soc. N. S. Wales, 48 (1914), No. 3, pp. 319-332).—In the course of an investigation on the physico-chemical constants of milk the author has observed that the velocity constant in the catalase reaction varies considerably in different

samples. This variation may be accounted for by the production of the catalase by bacteria in the milk while still in the udder, or later by bacteria from the air.

The rate of destruction of milk catalase is greatly increased by the rise of temperature. Potassium cyanid and hydrogen cyanid, although decreasing the activity of the enzym, have the effect of causing the enzym to decompose a greater amount of hydrogen peroxid. It is concluded that "there appears to be no doubt that the catalase of milk is analogous to the catalase obtained from blood."

The persistence of hydrogen peroxid in milk, E. Hinks (Analyst, 40 (1915), No. 477, pp. 482-491).—The length of time during which varying concentrations of hydrogen peroxid persist in both fresh and old milk and the influence of temperature on its persistence was studied.

It was found that hydrogen peroxid is at first rapidly destroyed but that the rate of destruction gradually diminishes. If the concentration of peroxid is high enough to withstand the rapid initial destruction the residual peroxid remains fairly constant over long periods of time. Fresh milk destroys hydrogen peroxid less readily than 3-day-old milk. The effect of a rise in temperature was to lengthen the time during which peroxid persisted, but the initial destruction was found to be greater at the elevated temperature. It is concluded that the ultimate result must be due to the combined destructive effect of the catalase on the peroxid and of the peroxid on the catalase.

Of the reagents used for the peroxidase reactions paraphenylenediamin was found to be the most generally applicable. On account of the destruction of peroxidase by peroxid it is necessary when testing for the latter to add some fresh milk to the sample in order to insure the presence of peroxidase. In applying the peroxidase reactions for the detection of previous heating the possibility of the milk having received an addition of peroxid must be considered, for a milk containing peroxid and a heated milk will, under certain circumstances, react in exactly the same manner.

Commercial and industrial analysis (organic), G. Halphen and C. Quillard (La Practique des Essais Commerciaux et Industriels; Matières Organiques. Paris: J. B. Baillière & Sons, 1915, 3. ed., rev. and enl., pp. VII+349, figs. 79).—This volume outlines in detail procedures for the examination and analysis of amylaceous materials, spices, sugar materials and products, liqueurs and other fermented beverages, milk, cheese, edible oils, waxes, resins, caoutchouc, mineral oils, fuel, coal-tar products, fats, paper, textiles, tanning materials and leather. The microscopical as well as the chemical analysis is considered.

Boiling and condensing points of alcohol-water mixtures, P. N. Evans (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 260–262, fig. 1).—The relation between the boiling point (or condensing point) and the composition of both the liquid and vapor phases of various mixtures of alcohol and water has been determined. These data are presented in tabular form and are of value in determining the quantity of alcohol present in an unknown mixture from its boiling point. The accuracy of the results by this procedure is necessarily less than by the more difficult method of distillation and the determination of the specific gravity of the distillate with a pycnometer.

The electrolytic determination of iodin present in organic matter, R. B. Krauss (Jour. Biol. Chem., 24 (1916), No. 3, pp. 321-325).—In the proposed method, which is described in detail, palladium is first deposited from an ammoniacal solution of palladous iodid on a platinum cathode, and the iodin subsequently on a silver anode. The new procedure provides an adequate check on a series of determinations by the palladous iodid colorimetric method, previously described by the author (E. S. R., 34, p. 504), but is far less sensitive.

A proposed new method for citrate-insoluble phosphoric acid, C. H. Hunt (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 251–253).—Confirming the findings of previous investigators, the author has shown that lime, limestone, and other calcium compounds increase the citrate-insoluble phosphoric acid. The ratio between the lime, determined as such, and the citrate-insoluble phosphoric acid has been shown to be fairly constant.

"In the proposed method the fertilizer is digested as for total phosphoric acid. An aliquot is made alkaline with ammonia and the phosphoric acid is determined in the precipitate thus formed. The ratio between the citrate-insoluble phosphoric acid and the phosphoric acid precipitated with ammonia is about 1:1.5. By dividing the amount of phosphoric acid precipitated with ammonia by 1.5 we obtain a figure which is approximately equal to the citrate-insoluble phosphoric acid determined by the official method. The plus and minus errors in the final results nearly balance each other.

"The fact that the errors for bone meal are nearly the same, and that for tankage and complete fertilizers are also nearly the same but of opposite quantity, seems to suggest a possibility of using a different factor for different types of fertilizers. The difference between the results obtained by the official and proposed methods is no greater than the differences in the results obtained by different analysts working on the same sample when the official method is used. The proposed method claims to be much shorter and less expensive, doing away with the use and preparation of neutral ammonium citrate."

The determination of citric-acid-soluble phosphoric acid in Thomas slag by the iron-citrate method, Celichowski and F. Pilz (Ztschr. Landw. Versuchsw. Österr., 18 (1915), No. 10, pp. 581-591).—It has been shown that in the preparation of the iron-citrate solution a clear, fresh solution of iron chlorid can be used. Old solutions which are partly decomposed and contain colloidal iron oxid are to be avoided. The iron-citrate solution used in the determination must not be too old, as it may influence the results due to partial dissociation. The hydrogen-peroxid solution should be comparatively fresh and controlled by testing from time to time. In the determination the reagents should be added to the citric acid extract in the following order: Iron-citrate solution, hydrogen peroxid, and magnesium mixture. To insure a rapid separation of the magnesium precipitate the solution should be strongly agitated.

The determination of potassium in fertilizers, F. Pilz (*Ztschr. Landw. Versuchsw. Österr.*, 18 (1915), No. 4-5, pp. 77-108.)—From preliminary experiments the author has developed a method for the determination of potassium in separate (potassium chlorid, kainit, kieserite, etc.) and mixed potassium fertilizers (potassium superphosphate, wood ashes, etc.) similar to the perchlorate method. The procedure is described in detail and tables for the conversion of KClO₄ into K₂O appended.

Note on the estimation of fat in food for infants, H. G. CHAPMAN (Jour. and Proc. Roy. Soc. N. S. Wales, 48 (1914), No. 3, pp. 469-472).—Certain discrepancies in the estimation of fat in infant foods by different procedures are reported.

The analysis of maple products.—VI, A volumetric lead subacetate test for purity of maple sirup, J. F. SNELL, N. C. MACFARLANE, and G. J. VAN ZOEREN (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 241–243, fig. 1).—The volumetric lead subacetate method proposed by the authors consists in diluting the sirup to 10 times its original volume and titrating with a standard subacetate solution, the end point being measured by electrical resistance. The volumetric lead number is then the abscissa of the point of intersection of two straight lines on the plot, with volumes as abscissæ and resistances as ordinates. It is concluded that if future work corroborates the past experience

of the reliability of the method the test will prove the most useful single test for the purity of maple products yet proposed.

Experimental data obtained by the proposed volumetric lead method and by the Canadian lead number method from 20 samples are submitted.

The determination of cholesterol in blood, W. R. Blook (Jour. Biol. Chem., 24 (1916), No. 3, pp. 227-231).—The author describes a quantitative colorimetric procedure for the determination of cholesterol, based on the Liebermann-Burchard color reaction.

The method consists of slowly adding from a pipette 3 cc. of whole blood, plasma, or serum to 75 cc. of alcohol-ether (3:1) mixture, contained in a 100 cc. graduated flask. The contents of the flask are kept in motion to avoid clumping of the precipitated material, and raised to boiling by immersion in a water bath. The flask is then cooled to room temperature, filled to the mark with the alcohol mixture, thoroughly mixed, and filtered. Ten cc. of this extract is evaporated to dryness in a small beaker, care being taken to prevent overheating, and the cholesterol extracted from the dry residue by boiling out three or four times with small portions of chloroform and decanting into a 10 cc. glass-stoppered, graduated cylinder. This solution should be colorless but not necessarily clear. To this, 2 cc. of acetic anhydrid and 0.1 cc. concentrated sulphuric acid are added, the solution well mixed, and then allowed to set in the dark for 15 minutes. The color thus produced is compared to that produced by a standard solution of cholesterol in chloroform, in a Duboscq colorimeter. The cement of the colorimeter cups must not be soluble in chloroform. Plaster of Paris or ordinary glue have been found satisfactory if the cups are not used for any other purpose.

The error of the above method is from 4 to 5 per cent. Greater accuracy may be obtained at the expense of more material and time. Experimental results obtained with the new procedure average about 20 per cent higher than those obtained by the Autenrieth-Funk method.^a

The volumetric estimation of total sulphur and sulphates in small quantities of urine, J. C. Drumond (Biochem. Jour., 9 (1915), No. 4, pp. 492–507).—An improved procedure of the benzidin method of Raiziss and Dubin (E. S. R., 33, p. 415) for the determination of sulphur in urine and other biological material, in which as little as 2 cc. of sample can be used, is described. The precipitated benzidin sulphate is titrated with a $\frac{1}{100}$ -normal alkali.

A method for the determination of alcohol in the presence of phenol, J. Ehrlich (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 240, 241).—The author has observed that, in the usual method of determining ethyl alcohol in the presence of phenol by means of distillation from strongly alkaline solution, a trace of phenol resulting from the partial hydrolysis of the phenolate is always carried over in the distillate.

To obviate this source of error in the method proposed, any phenol that may be carried over in the first distillation is precipitated with bromin, the slight excess of bromin being immediately removed with normal sodium thiosulphate. The precipitated tribromphenol is dissolved as the phenolate by alkali, the mixture again distilled, and the alcohol thus determined.

If the original phenol content is low the first distillation may be omitted. If there is a great amount present two distillations are necessary, as the bulky precipitate of tribromphenol makes it impossible to perceive when an excess of bromin is present.

Experimental results submitted indicate the great accuracy of the procedure.

^a München Med. Wehnschr., 60 (1913), No. 23, pp. 1243-1248.

A rapid pycnometric method for "gravity solids" in cane-sugar factories, H. S. Walker (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 262-264).—A procedure using a modified pycnometer with specially constructed correction tables is described in detail. In the proposed method the average error is greatly reduced.

Theories on the formation of molasses from the standpoint of phases, T. VAN DEN LINDEN (Meded. Proefstat. Java-Suikerindus., 5 (1915), Nos. 14, pp. 419-436, figs. 5; 16, pp. 447-476, figs. 10; Arch. Suikerindus. Nederland. Indië, 23 (1915), Nos. 27, pp. 1033-1050, figs. 5; 37, pp. 1389-1418, figs. 10).—The author reports the results of his investigation of the 3-phase system, saccharose and nonsaccharose material and water, and indicates its probable application in practical sugar manufacture.

A proposed method for the profitable utilization of waste sulphite liquor, H. V. Tartar (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 226-228).—As the result of an investigation to determine the possibility of utilizing waste sulphite liquors, conducted in an experimental distillery at the Oregon Experment Station, a simple and easily controlled process for the economic production of alcohol from the liquor was developed. In the process the sulphite liquor is so detoxicated as to make it, when properly diluted, practically harmless to fish.

Fruit preserving: Canning, bottling, jam-making, and candying peel, W. J. Allen (Dept. Agr. N. S. Wales, Farmers' Bul. 88, 2. cd. (1915), pp. 43, figs. 27).—This is the second edition of the publication previously noted (E. S. R., 32, p. 509). Some new material on the canning of vegetables has been added.

METEOROLOGY.

Climatic variations and economic cycles, E. Huntington (Geogr. Rev., 1 (1916), No. 3, pp. 192-202, figs. 4).—This is a critical review of recent contributions to this subject, particularly those of Moore and Pettersson. It is pointed out that, from a study of the rainfall in the Ohio Valley and Illinois and its relation to the growth of corn, oats, hay, and potatoes, Moore concludes a that "'the weather conditions represented by the rainfall in the central part of the United States, and probably in other continental areas, pass through cycles of approximately 33 years and 8 years in duration, causing like cycles in the yield per acre of the crops. . . . The rhythm in the activity of economic life, the alternation of buoyant, purposeful expansion with aimless depression, is caused by the rhythm of the yield per acre of the crops; while the rhythm in the production of the crops is, in turn, caused by the cyclical changes in the amount of rainfall. The law of the cycles of rainfall is the law of the cycles of crops and the law of economic cycles.'" Essentially the same conclusions have been reached by Pettersson, Clayton, Brückner, and others.

Various hypotheses as to cyclic changes in climate are briefly discussed in their relation to their economic effects on man, plants, and animals.

The money value of rainfall in selected crop areas of the United States, E. J. Cragoe (Jour. Geogr., 14 (1915), No. 1, pp. 1-6; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1574, 1575).—This article gives in brief the results of an attempt to work out the correlation of rainfall to wheat and corn production in definite mathematical form. For example, it is calculated from the available data that the average wheat yield (bushels per acre) is about twice the number of inches of average

^a Economic Cycles: Their Law and Cause, H. L. Moore, New York: The Macmillan Co., 1914, p. 149.

rainfall of May and June in North Dakota, 1.7 times the rainfall of these months in South Dakota, about the same as the inches of rainfall during January, February, March, and April in California, four times the inches of rainfall during these months in Washington, and less than twice the inches of rainfall of March, April, and May in Kansas and Nebraska.

In regions of ordinarily abundant (as compared with regions of deficient) rainfall, like Minnesota, Ohio, Indiana, Illinois, and Missouri, there was found to be no direct relation between wheat yield and average rainfall. "The results in all cases indicate, however, that the best crops can be expected when the rainfall is below the normal amount during the critical months of the growing season." It was found that "in average years, the yield of corn throughout the corn belt was approximately eight times the July rainfall. In the best years, however, the yield was only seven times the rainfall for this month, and in the poorest years it was ten times as great."

Correlations are made of the approximate money value of different amounts of rainfall to each crop in the area of deficient rainfall.

Protection from damage by frost, W. G. Reed (Geogr. Rev., 1 (1916), No. 2, pp. 110-122, figs. 8).—Conditions of frost occurrence, frost damage, methods of protection, and frost forecasting are briefly discussed. The conclusion is reached that the low temperatures resulting in frost injury "can be prevented by heating the lower air to supply the loss of heat to the cold earth and by checking radiation from the earth; mixing the air is not now practicable. The methods most successful commercially depend upon the combination of heat and smoke. The best practice is fairly clean-burning small fires, one to each one or two trees."

Relation of the soil to meterological factors, E. G. LOSKE (*Trudy Selsk. Khoz. Met.*, Nos. 8 (1911), pp. XII+104; 9 (1912), pp. XIV+105-334; 11 (1915), pp. XVII+335-600).—The literature of investigations bearing on the subject is exhaustively reviewed and digested.

Aridity and humidity maps of the United States, M. Jefferson (Geogr. Rev., 1 (1916), No. 3, pp. 203-208, figs. 2).—Two maps are described in which an attempt has been made to represent simply and clearly the essential facts of rainfall "that condition life in the United States."

Agricultural meteorology in Canada, R. W. Mills (Agr. Gaz. Canada, 3 (1916), No. 2, pp. 177-179).—This article briefly explains the purpose and plan of the work of the department of agricultural meteorology of the Meteorological Service of Canada, which was organized in 1914 to study the relation of meteorological conditions to crop growths by methods similar to those employed in Russia.

It is stated that 14 stations well distributed over Canada were in operation in 1915 for the purpose of studying the relation of meteorological factors to the growth of spring wheat. The plan followed called for the collection of information regarding "(1) general field conditions and the farming methods employed, (2) dates of the important stages in the life of the wheat, from sowing to reaping, and the general condition of the plants at the time of the stages, (3) average height of plants on the plat every seven days, (4) the damaging effect of adverse weather phenomena on plants and soil, at any time throughout the season, losses due to meteorological and to other factors, and (5) final yield and quality." By means of a graphical method the crop notes are compared with charts showing the daily temperature, precipitation, and bright sunshine at each station throughout the growing season.

[Report of the] committee for the investigation of atmospheric pollution (Lancet [London], No 9 (1916), I, Sup., pp. I-XL, figs. 18).—This is the first report of the committee and covers the investigations from April, 1914, to

March, 1915. It describes the methods and apparatus adopted and results (in detail) obtained in a systematic study of the pollution of the air in and around various English cities as indicated by measurement and chemical examination of the rain water and deposits collected in special gages devised for the purpose. The data include rainfall in millimeters, and tar, ash, total solids, soluble sulphates, chlorin, and ammonia expressed in metric tons per square kilometer.

SOILS-FERTILIZERS.

A guide to the mineralogical analysis of soil, F. SEEMANN (Leitfaden der Mineralogischen Bodenanalyse. Vienna: Wilhelm Braumüller, 1914, pp. IX+110, pls. 3, figs. 39).—This book represents the author's experience as a teacher of mineralogical soil analysis, in which an effort is made to correct some of the faults of earlier methods.

The volume is divided into the following main parts: Collecting of sample; investigation of the most important physical properties of the soil; mechanical soil analysis; and mineralogical examination of soil constituents, embracing (1) methods and (2) character of the soil-forming minerals. Seven tables for the determination of minerals in the soil are included.

The data of geochemistry, F. W. CLARKE (U. S. Geol. Survey Bul. 616 (1916), pp. 821).—This is the third edition, revised and enlarged, of this work (E. S. R., 26, p. 517).

The plasticity of clay and its relation to mode of origin, N. B. Davis (Trans. Amer. Inst. Mining Engin., 51 (1916), pp. 451-480, figs. 4).—Plasticity is defined, especially with reference to clay, and theories of plasticity as developed by others, based on (1) structure of clay particles, (2) presence of hydrous aluminum silicates, (3) molecular attraction between particles, and (4) presence of collodial gelatinous matter, are reviewed and discussed. The theory of suspension and emulsion colloids is reviewed and experiments on the plasticity of four excessively plastic clays are reported. A further study deals with the formation of residual and transported clays.

It is concluded that "plasticity in clays is due to the gelatinous state of matter, a state common to them because of their mode of origin. This gelatinous matter may be silicic acid gel, alumina gel, iron oxid gels, silicate gels, or organic gels. Two or more of these are usually present, and their effect will be further modified by adsorbed salts and the relative proportions of large and small grains, and to a limited extent by the shape of the grains. The particular kind and amount of gelatinous matter present, the size and shape of grain, and the relative proportions of large and small grains, are important factors in determining the other related physical properties of tensile strength and air shrinkage."

On osmosis in soils, C. J. Lynde and J. V. Dupré (Proc. and Trans. Roy. Soc. Canada, 3. ser., 9 (1915), Sect. III, pp. 69-80, figs. 2; Jour. Amer. Soc. Agron., 7 (1915), No. 6, pp. 283-292, figs. 2).—Further experiments on the subject with a moist clay subsoil (E. S. R., 33, p. 420), for the purpose of testing phenomena observed in previous experiments, are reported. The general conclusion is drawn that "whatever the cause, water moves through clay subsoil from a weak soil solution toward a strong one. The results agree with the theory that this movement is caused by osmosis."

Salts, soil colloids, and soils, L. T. Sharp (*Proc. Nat. Acad. Sci., 1* (1915), No. 12, pp. 563-568).—This is a general discussion of the results of investigations, to be reported in detail later, on the subject of salts in relation to soil colloids. The experiments are based largely on the striking change in physical

properties produced in soils on the addition and subsequent leaching out of salts. An attempt is made to explain this change on the basis of colloid chemistry, especially "on the contention that the behavior of soils under the influence of salts agrees in some measure with the laws which are thought to govern the behavior of dispersed systems to which salts have been added."

The adsorption of potassium and phosphate ions by typical soils of the Connecticut Valley, R. H. Bogue (Jour. Phys. Chem., 19 (1915), No. 8, pp. 665-695, figs. 13).—Experiments conducted at the Massachusetts Agricultural College with sand, fine sandy loam, silt loam, and clay soils to determine their adsorptive powers for potassium and phosphate ions from percolating solutions of monocalcium phosphate and potassium chlorid of concentrations equivalent to 200 parts per million of potassium and phosphoric acid, respectively, are reported. The results are presented in tabular and graphic form.

It was found that "when soils are subjected to the leaching action of water, the concentration of potassium and phosphate ions in the soil extract approaches a constant which appears to be fixed and definite for any given soil. When soils are subjected to the action of soluble potassium and phosphate salts, the concentration of these salts in the soil extract is at first not materially increased owing to the power of the soils to adsorb these salts, but as adsorption proceeds it becomes weaker and a point is finally reached where the amount of soluble salts in the soil extract is nearly equivalent to the amount applied. The concentration of the potassium and phosphate ions in the soil extract approaches a low constant, which appears to be fixed and definite for each soil, when only a part of the adsorbed ions has been removed by the leaching action of water.

"The constants attained by the four soils by the leaching action of water are very nearly alike, which would seem to indicate that the concentration of the potassium and phosphate ions in the soil solutions of the various soils were practically the same, and not at all dependent on the amount of adsorbed potassium or phosphate they originally contained. These results substantiate the theory that the concentration of salts in the soil solution is very largely dependent on the specific adsorptive capacity of the individual soil . . . [They] tend to disprove the theory that the composition of the soil moisture, hence the adsorptive capacity of the soil, is determined primarily by the chemical composition of the soil, but tend rather to prove this quality to be dependent on the mechanical texture of the individual soil."

The results are also taken to indicate that the soils were able to take up the potassium and phosphoric acid by both physical and chemical processes.

Soil survey of Mississippi County, Arkansas, E. C. Hall, T. M. Bushnell, L. V. Davis, W. T. Carter, Jr., and A. L. Patrick (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 42, pl. 1, fig. 1, map 1).—This survey, issued April 4, 1916, deals with the soils of an area of 575,360 acres in northeastern Arkansas which lies within the River Flood Plains soil province and comprises first and second bottom lands. In general the topography varies little from a nearly flat and level plain. The natural drainage of the county is generally poor owing to the low-lying position of the soils and to the annual overflows of the Mississippi River. The soils range from loose, incoherent sands to heavy, plastic clays and are of alluvial origin. Including meadow and overwash, 22 soil types of 6 series are mapped, of which the Sharkey clay covers 64.7 per cent of the area.

Soil survey of Webster Parish, Louisiana, A. H. MEYER, E. S. VANATTA, B. W. TILLMAN, and R. F. ROGERS (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 40, fig. 1, map 1).—This survey, made in cooperation with the Louisiana Experiment Station and issued March 11, 1916,

deals with the soils of an area of 389,760 acres in northwestern Louisiana which lies wholly within the Coastal Plain province. The topography varies from flat to rolling and consists of sedimentary uplands, alluvial terraces, and first bottom lands. In addition to meadow, 21 soil types of 11 series are mapped, of which the Ruston, Susquehanna, Ocklocknee, and Lufkin very fine sandy loams cover 30.9, 12.4, 10, and 9.9 per cent of the area, respectively.

Soil survey of Montgomery County, Maryland, W. T. CARTER, JR., and J. P. D. Hull (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 39, pls. 5, fig. 1, map 1).—This survey, made in cooperation with the Maryland Geological Survey and issued March 25, 1916, deals with the soils of an area of 309,760 acres in the center of the southwestern boundary of Maryland.

"The topography varies from almost level or gently rolling to strongly rolling and hilly, being prevailingly rolling. . . . Throughout the county the surface drainage is good." The area lies almost entirely within the Piedmont Plateau province, only a narrow strip being in the Coastal Plain province. The soils are grouped as (1) residual soils and (2) soils derived from the unconsolidated material of the Coastal Plain and recently deposited material along streams. Seventeen soil types of 13 series are mapped, of which the Chester loam is the most extensive type and is considered the most important soil in the county. It covers 40.4 per cent of the area and the Manor loam covers 16.9 per cent.

Soil survey of Clinton County, New York, E. T. Maxon and W. R. Cone (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 37, fg. 1, map 1).—This survey, made in cooperation with the New York State College of Agriculture and issued March 18, 1916, deals with the soils of a well-drained area of 671,360 acres in northeastern New York. The topography is rolling to hilly and precipitous. The soils are of glacial, lacustrine, and alluvial origin. Exclusive of six miscellaneous types, 26 soil types of nine series are mapped, of which the Coloma soils are the most extensive types, the Coloma stony fine sandy loam and fine sandy loam covering 21.5 and 17.1 per cent of the area, respectively. The Gloucester stony fine sandy loam covers 13.9 per cent of the area.

Soil survey of Trumbull County, Ohio, G. N. COFFEY, J. WOODWARD, and J. M. SNYDER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 53, figs. 2, map 1).—This survey, made in cooperation with the Ohio Experiment Station and issued March 21, 1916, deals with the soils of an area of 405,120 acres in northeastern Ohio, the surface of which is level to rolling with some small areas of steep and hilly land.

Trumbull County lies entirely within the late Wisconsin glaciation and the soils are almost entirely of glacial origin. Including muck and peat, 23 soil types of 11 series are mapped, of which the Volusia clay loam and silt loam cover 23.2 and 20.3 per cent of the area, respectively, and the Trumbull clay loam and silt loam 13.9 and 10 per cent of the area, respectively.

Soil survey of Raleigh County, West Virginia, W. J. LATIMER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 34, fig. 1, map 1).— This survey, made in cooperation with the West Virginia Geological Survey and issued March 28, 1916, deals with the soils of an area of 391,040 acres in southern West Virginia lying wholly within the Allegheny Plateau. The greater part of the surface of the county is extremely rough and dissected. The soils are of residual, old alluvial, and alluvial origin. Including rough stony land, 14 soil types of 5 series are mapped, of which the Dekalb series, including silt loam, stony silt loam, silty clay loam, stony loam, loam, and fine sandy loam, constitute 82.8 per cent.

Soil survey of Fond du Lac County, Wisconsin, A. R. WHITSON, W. J. Geib, L. R. Schoenmann, F. L. Musbach, G. Conrey, and A. E. Taylor (Wis. Geol. and Nat. Hist. Survey Bul. 37 (1914), Soil Ser. 7, pp. 84, pls. 5, figs. 2, map 1).—This survey, made in cooperation with the Bureau of Soils of this Department, was noted in the report of the field operations of that Bureau for 1911 (E. S. R., 31, p. 513).

Soil survey of Juneau County, Wisconsin, A. R. WHITSON, W. J. Geib, L. R. Schoenmann, C. A. Leclair, O. E. Bakeb, and E. B. Watson (Wis. Gcol. and Nat. Hist. Survey Bul. 38 (1914), Soil Ser. 8, pp. 92, pls. 5, figs. 2, map 1).—This survey, made in cooperation with the Bureau of Soils of this Department, was noted in the report of the field operations of that Bureau for 1911 (E. S. R., 31, p. 513).

Soil survey of Kewaunee County, Wisconsin, A. R. Whitson, W. J. Geib, E. J. Graul, and A. H. Meyer (Wis. Geol. and Nat. Hist. Survey Bul. 39 (1914), Soil Ser. 9, pp. 83, pls. 3, figs. 2, map 1).—This survey, made in cooperation with the Bureau of Soils of this Department, was noted in the report of the field operations of that Bureau for 1911 (E. S. R., 31, p. 513).

Soil survey of La Crosse County, Wisconsin, A. R. Whitson, W. J. Geib, T. J. Dunnewald, and C. Lounsbury (Wis. Geol. and Nat. Hist. Survey Bul. 40 (1914), Soil Ser. 10, pp. 76, pls. 5, figs. 2, map 1).—This survey, made in cooperation with the Bureau of Soils of this Department, was noted in the report of the field operations of that Bureau for 1911 (E. S. R., 31, p. 513).

The chemical composition of virgin and cropped Indiana soils, S. D. Conner (Proc. Ind. Acad. Sci., 1914, pp. 359–363).—Chemical analyses, made at the Indiana Experiment Station, of 31 composite samples of virgin and cropped Indiana soils and subsoils (the top 6.5 in. and the layer from a depth of 12 to 18 in.) show that "the most serious losses from the standpoint of soil fertility are those of nitrogen, which shows a loss of 28 per cent, and the organic matter, which shows a loss in the volatile matter of 26 per cent and in the humus of 47 per cent. . . While the phosphoric acid and potash show only about 10 per cent loss this 10 per cent was the most available portion of these important elements." There was little difference in the contents of sulphur, calcium, and magnesium in virgin and cropped soils, but quite a loss of manganese in the cropped soil. "While the acidity of the cropped soil has increased, the acidity of the cropped subsoil has decreased."

Plant food in Aroostook soils, C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 14-16).—Analyses of ten samples of the soils of Aroostook County, Me., are reported showing total nitrogen varying from 0.113 to 0.281 per cent, potash soluble in hot strong hydrochloric acid varying from 0.27 to 0.369 per cent, phosphoric acid soluble in hot strong hydrochloric acid varying from 0.151 to 0.32 per cent, and lime varying from 0.11 to 0.31 per cent.

A peculiar clay from near the City of Mexico, E. W. HILGARD (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 1, pp. 8-12).—Attention is drawn to a new type of so-called clay soil, samples of which were obtained from an unproductive farm in the vicinity of Mexico City, Mexico.

The clay showed marked swelling properties in contact with water and was very plastic when wet. After protracted boiling of a sample of the clay "the suspension . . . showed a multitude of dark rounded particles, very uniformly distributed through a colloidal medium of faintly yellowish tint. . . . All attempts to free the colloidal ingredients from the visibly discrete particles by sedimentation proved futile. The suspension was readily coagulated and precipitated, apparently unchanged, by a solution of sodium chlorid. On washing by decantation the suspension was again readily made, the microscopic character also remaining the same."

Data from chemical analyses of the clay "show clearly a totally different composition from any 'clay' on record. The alumina present is far below any reasonably assumable compound with the soluble silica; the predominant base being evidently magnesia, and that greatly in excess of the lime present."

The name Lucianite is suggested.

Analyses of Queensland soils, J. C. Brunnich (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1914–15, pp. 34–49).—Chemical analyses of 152 samples and physical and mechanical analyses of 136 samples of Queensland soils are reported.

Some preliminary investigations into the chemical composition of certain vineyard soils in the Montagu and Robertson districts, A. I. Perold and D. C. Crawford (So. African Jour. Sci., 11 (1915), No. 9, pp. 337-349).—Analyses of 80 samples of the soil, and where possible of the subsurface and subsoil, from these two districts of Cape Colony are reported and discussed. The samples were taken at three depths, namely, from 0 to 12 in., from 12 to 30 in., and from 30 to 48 in. The soils are of alluvial and residual origin, the former varying in texture from loose loams to heavy clay loams, and the latter being nearly all of a clayey nature.

The results of the analyses are taken to indicate that the nitrogen and phosphoric acid contents of these soils are relatively low, while the contents of potash and lime in most cases reach the average and in some cases exceed it. Many of the soils showed a lower potash content than the corresponding subsoils, especially the residual soils. The nitrogen and phosphoric acid contents of the subsoils were almost invariably less than those of the surface soils.

Relation of carbon bisulphid to soil organisms and plant growth, E. B. Fred (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 1, pp. 1–19, pls. 2).—Experiments conducted at the Wisconsin Experiment Station on the effect of carbon bisulphid (1) on the number and activity of soil organisms of a silt loam soil, (2) on buckwheat, clover, corn, mustard, oats, and rape in silt loam soil and in silt loam and sand mixed, sand, clay, loam, silica sand, and acid soil, and (3) on reinoculated soil and the accumulation of sulphates in soil are reported, continuing previous work (E. S. R., 27, p. 131). The following conclusions are drawn:

"The addition of carbon bisulphid to soil exerts a decided effect on the fauna and flora of the soil, characterized by a temporary reduction in the number of micro-organisms. Later, an enormous multiplication of bacteria takes place and an almost parallel increase in production of by-products or soluble nitrogen is noted. The ammonia content seems to follow the curve of bacterial growth and later gives way to larger amounts of nitrate. . . . It seems that carbon bisulphid in soil produces an increase in soluble compounds of nitrogen and sulphur.

"In Miami soil carbon bisulphid benefited the growth of buckwheat, oats, and mustard. No relation seems to exist between plant stimulation with carbon bisulphid and the form of the soluble nitrogen. In nonacid soils carbon bisulphid is most beneficial to sulphur crops. Mustard offers a good example. In all of the experiments, except on acid soils, mustard showed an increased growth from the use of carbon bisulphid. Carbon bisulphid in peat soil greatly benefits the growth of red clover. In sand cultures plus soluble plant food carbon bisulphid favors the growth of certain plants.

"The data show clearly that carbon bisulphid does not act alike in all soils or toward all crops."

The effect of heat upon soil fertility, W. L. OWEN (Sugar [Chicago], 17 (1915), No. 10, pp. 31, 32).—This is a brief review of work by others on partial

sterilization of soils by antiseptics and heating. It is thought that the benefits which result from heating the soil are partly biological and partly chemical.

The influence of nitrification upon soil fertility, W. L. OWEN (Sugar [Chicago], 17 (1915), No. 11, pp. 30, 31).—From a review of work bearing on the subject conducted at some of the state experiment stations and at foreign experiment stations, the author concludes that cotton-seed meal is superior to ammonium sulphate, due to the neutralization of the soil acidity in the former case by the formation of ammonia.

Physical-chemical studies of soil.—III, The conditions of humidity of soils and the absence of vegetation, U. Pratolongo (Staz. Sper. Agr. Ital., 48 (1915), No. 1, pp. 44–56; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 5, p. 660).—Experiments, based in part on work previously noted (E. S. R., 30, p. 215), with rye, oats, clover, vetch, mustard, and flax, on four different arable soils of alluvial origin, and one clay soil, are reported. The purpose was to determine the relation between the initial wilting point of the plant on the one hand and the water content of the soil at the initial wilting point and the chemical and physical properties of the soil on the other. In the experiments normal conditions were maintained during the germination and growth of the crops until a height of from 10 to 12 cm. (3.94 to 4.73 in.) was reached, after which all conditions were maintained normal except moisture, the content of which was gradually decreased.

It was found that a constant relation existed between the water contents of the different soils at the initial wilting point of vegetation and the so-called "deviation" in the Van Bemmelen water vapor tension curve for the same soils, the average coefficient of proportionality being 5.06±0.08. No essential difference was observed in the different crops in regard to their resistance to the gradually increasing aridity of the soils.

Effect of vanillin as a soil constituent, J. J. SKINNER (*Plant World*, 18 (1915), No. 12, pp. 321-330, figs. 5).—The substance of this paper has been previously noted from another source (E. S. R., 32, p. 619).

Experiments on lime determination in agricultural soil by more recent methods, W. Bandi (Jahresber. Landw. Schule Rütti, 1912–1914, pp. 149–154).— Experiments with 130 samples of soils of varying textures are reported, in which the extent of effervescence with hydrochloric acid, the amount of calcium oxid soluble in ammonium chlorid, the reaction to litmus, and the power of sustaining the development of Azotobacter in a nutritive medium were observed for each sample.

The results are taken to indicate that the simple hydrochloric acid test for the lime requirement of soil is in general sufficient. If a soil effervesces with hydrochloric acid it is considered to need no lime. A quantitative determination of carbon dioxid is considered superfluous on the grounds that the hydrochloric acid test is equally effective within practical limits. On the other hand, if there is no effervescence with hydrochloric acid the reaction toward litmus should be determined. If alkaline, this indicates that no lime is needed, but if acid, shows a need for lime. If the reaction toward litmus is neutral the power of supporting a growth of Azotobacter should be tested.

See also previous notes by Christensen (E. S. R., 24, p. 527; 34, p. 813).

Plant foods for crops in 1916, L. L. VAN SLYKE (New York State Sta. Circ. 47 (1916), pp. 8).—This circular presents the consensus of opinion of the members of a conference of representatives of the agricultural experiment stations of the New England States, New Jersey, and New York called for the purpose of discussing the effects of the war upon the cost of plant-food materials and furnishing suggestions to farmers as to practical methods to adopt during 1916 under present conditions.

Experiments with fertilizers, F. E. Bear (West Virginia Sta. Bul. 155 (1915), pp. 19, figs. 11).—This bulletin gives the results to date of experiments partly reported upon in previous bulletins of the station (E. S. R., 24, p. 716).

A summary of the 15 years' experiments indicates that every ton of manure applied alone has produced an increase per ton valued at \$3.12, and that for every dollar invested in them acid phosphate, sodium nitrate, and potassium sulphate when applied alone have given average increases valued at \$4.63, 34 cts., and 37 cts., respectively. Sodium nitrate and acid phosphate applied in combination gave two and a quarter times as much increase per acre as acid phosphate alone, and sodium nitrate, potassium sulphate, and acid phosphate applied in combination gave three times as much increase per acre as acid phosphate alone. Every dollar invested in lime and applied in connection with complete fertilizer gave an increase valued at \$1.35.

It is concluded that acid phosphate is of great importance as a fertilizer in the State. From the results obtained with acid phosphate and sodium nitrate it is further concluded "that if more legumes had been grown on the soil and the amount of nitrogen in the soil had been increased thereby we could expect a greater return from the use of acid phosphate on the plat receiving acid phosphate alone."

Culture experiments with nitrogenous fertilizers, A. von Reibnitz (Ztschr. Landw. Kammer Schlesien, 19 (1915), Nos. 18, p. 536; 19, pp. 567, 568).—Two years' field experiments with sugar beets and wheat on a mild loam soil to determine the relative fertilizing values of lime nitrogen, Norwegian nitrate, and sodium nitrate, when added in amounts equivalent to 15 and 25 lbs. of nitrogen per acre, showed that lime nitrogen had practically no effect on the beets, while Norwegian nitrate and sodium nitrate caused marked and about equal increases. Both the nitrates had a much more favorable effect on wheat than lime nitrogen. It is considered inadvisable, therefore, to use lime nitrogen on beets or to use more than 10 lbs. of nitrogen per acre in the form of lime nitrogen on wheat. It is thought further that lime nitrogen should be applied some time before seeding and be thoroughly mixed with the soil.

Granulated calcium cyanamid (Norwegian lime nitrogen), S. Hals (Tidsskr. Norske Landbr., 22 (1915), No. 8, pp. 332-340; Zentbl. Kunstdünger Indus., 20 (1915), No. 21, pp. 264-266).—The process of manufacture of granulated Norwegian lime nitrogen is described and a comparison of its chemical composition with that of the common dusty cyanamid is drawn.

The results indicate that the solubilities in water of the nitrogen of the two fertilizers are about equal. The nitrogen in both fertilizers is present as calcium cyanamid and as dicyandiamid, the latter being the prevailing form in Norwegian lime nitrogen. The coarser grains of the Norwegian lime nitrogen were somewhat more slowly soluble in water than the finer grains. Norwegian lime nitrogen when mixed with superphosphate had a less marked tendency to fix the soluble phosphate in insoluble form than had cyanamid.

Acid soils and the effect of acid phosphate and other fertilizers upon them, S. D. Conner (Jour. Indus. and Engin. Chem., 8 (1916), No. 1, pp. 35-40, figs. 2).—Experiments on the effect of neutral normal solutions of salts on acid soils and of heat and phosphates on soil acidity are reported. The soluble salts used were the sulphate, acetate, chlorid, and nitrate of potassium, sodium, and magnesium, the acetate, chlorid, and nitrate of calcium, and the acetate and chlorid of barium.

It was found that "various acid constituents of soils show different degrees of reactivity with different bases, also with the same base when free or when combined with different acids. . . . When aluminum silicates are treated with a solution of potassium hydroxid, heat is developed with the acid silicates

but not with neutral silicates. The heat developed is proportional to the acidity, indicating a chemical rather than a physical reaction. The acidity of aluminum silicates is not only in proportion to the ratio of Al_2O_3 to SiO_2 but also in proportion to the water of constitution. The greater the proportion of water in the silicate the more acid is the reaction. Heating and the consequent driving off of water of constitution in acid aluminum silicates lower the acidity until all the water is removed when neutrality is reached. Ignition of acid soils also destroys the acidity. Much of the harmful acidity of acid soils is due to the presence of toxic acid salts of aluminum and iron. The immediate effect of the addition of soluble fertilizer salts of the strong acids (nitric, hydrochloric, and sulphuric) to acid soils is to increase the soluble acid salts of aluminum and iron."

In field and laboratory experiments it was found that "soils treated for 20 years with acid phosphate show less acidity than soils that have never had acid phosphate. Acid soils and silicates treated in the laboratory with acid phosphate show less soluble acidity than untreated soils and silicates."

A new method of estimating soil acidity, in which the catalysis of ethyl acetate is taken as a measure of the solubility, is described, which is used together with the potassium nitrate method of Hopkins, Knox, and Pettit and the limewater method of Veitch (E. S. R., 14, p. 111).

Phosphatic fertilizers and the root system of beets, V. I. SAZANOV (Zhur. Opytn. Agron., 16 (1915), No. 2, pp. 140-165, figs. 18; abs. in Chem. Abs., 9 (1915), No. 17, p. 2419).—Box experiments on chernozem soil to determine the influence of superphosphate on the development of the root system of beets are reported.

It was found that soluble phosphoric acid was fixed in the layer of chernozem soil to which it was added, and that no considerable amount of phosphoric acid was displaced and transferred from one layer to another. Superphosphate was favorable to the extensive development of beet roots, notably in the layer of soil to which it was added. No similar influence of superphosphate on the roots of wheat and rye was observed.

Phosphate rock, W. H. Waggaman (In *The Mineral Industry: Its Statistics*, *Technology, and Trade During 1914. New York and London: McGraw-Hill Book Co., 1915, vol. 23, pp. 584–601*).—This article deals with the production of phosphates in the United States and in foreign countries, it being stated that the world's production of phosphate rock in 1913 amounted to over 6,780,000 tons. In 1914 the total output was less than 4,000,000 tons, of which the United States produced 2,752,971 tons and consumed 1,823,978 tons. Methods for the production of soluble phosphate from phosphate rock are briefly described, and a bibliography of works bearing on the subject is appended.

Potassium salts, S. H. Dolbear (In *The Mineral Industry: Its Statistics*, *Technology, and Trade During 1914.* New York and London: McGraw-Hill Book Co., 1915, vol. 23, pp. 611–622).—This report deals with the sources and production of potash salts in the United States and foreign countries and the imports and exports of the same, with special reference to the years 1910 to 1914. A bibliography of works bearing on the subject is appended.

Investigation of sources of potash in Texas, W. B. PHILLIPS (*Trans. Amer. Inst. Mining Engin.*, 51 (1916), pp. 438–450, figs. 3).—This is a discussion of the potash resources of Texas, from which it is concluded that the only hopeful outlook for the existence of workable sources of potash salts in Texas is in the direction already indicated by Udden (E. S. R., 34, p. 26) and in the region southeast of and bordering on New Mexico.

Potassium salts in Catalonia, C. Rubio and A. Marín (Bol. Inst. Geol. España, 2. ser., 14 (1914), pp. 173-230; rev. in Econ. Geol., 10 (1915), No. 6, pp. 586-588).—This report deals mainly with the geology of the recently discovered deposits of potassium salts in Catalonia, Spain.

It is stated that the deposits of salts occur in a basin of marine sediments of Eocene and Oligocene age. The most important developments have been undertaken near the town of Suria. The tonnage of potassium salts in this neighborhood computed on a provisional basis is carnallite 2,550,000 tons and sylvinit 1,125,000 tons. It is stated that the carnallite of Suria is of a very red color and contains from 11.52 to 15.26 per cent of potassium oxid.

German and other sources of potash supply, C. H. MacDowell (*Trans. Amer. Inst. Mining Engin.*, 51 (1916), pp. 424-437).—A discussion is given of German and other sources of potash, with special reference to their commercial aspects.

Sodium and sodium salts, S. H. Salisbury, Jr. (In *The Mineral Industry: Its Statistics, Technology, and Trade During 1914. New York and London: McGraw-Hill Book Co., 1915, vol. 23, pp. 665–682).*—This report deals with the world's production of sodium salts, especially sodium nitrate, with special reference to 1914 and previous years. A bibliography of works bearing on the subject is appended.

Limestone: North Island analyses, B. C. Aston (Jour. Agr. [New Zeal.], 11 (1915), No. 3, pp. 235-240).—Analyses of 242 samples of limestone from North Island, New Zealand, are reported.

A waste lime product, C. E. THORNE (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 101, 102).—Attention is drawn to the value of the waste lime products from sodium carbonate factories as a lime fertilizer.

The use of peat in commercial fertilizer, H. E. WILDEMAN (Jour. Amer. Peat Soc., 9 (1916), No. 1, pp. 28-35).—A discussion of the use of peat as a fertilizer filler is given, together with a review of experiments from various sources on the availability of the nitrogen of peat.

AGRICULTURAL BOTANY.

Relation of green manures to the failure of certain seedlings, E. B. Fred (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 25, pp. 1161-1176, pls. 2).— In a previous report (E. S. R., 28, p. 816), a decreased germination of cotton was noted immediately following green manures. In the present paper the author describes a more extensive investigation of this phenomenon, conducted at the Wisconsin Experiment Station.

The results of a series of laboratory studies indicate that green manures may seriously injure the germination of certain seeds. This is believed to be brought about by the action of certain parasitic fungi, the development of which is favored by the decomposition of the green manure plants. As a rule, oil seeds are easily damaged, while starchy seeds on the contrary are quite resistant. Cotton seed and soy beans seem to be extremely sensitive to conditions resulting from green manuring, and the germination of flax, peanuts, hemp, mustard, and clover is reduced somewhat by the presence of decomposing plant tissue. The damage to oil seeds from green manuring seems to be confined largely to the first stages of decomposition, and experimental evidence seems to indicate that two weeks after green manure is added, it does not cause any injury to the seeds. Small applications of calcium carbonate seem to increase the injury to germination. The rate of germination was found to determine to a certain extent the degree of injury, slow germination being marked by a high percentage of diseased seedlings.

Activities of the micro-organisms of the soil (North Dakota Sta. Rpt. 1915, pt. 1, pp. 16, 17).—A study is in progress to determine and control the optimum conditions for the maximum efficiency of micro-organisms concerned in soil fertility. The work of the past year is said to have demonstrated that the energy material, consisting mainly of carbohydrates and their decomposition products, is the chief factor governing ammonification. As long as readily available energy material is present in excess of the required ratio to nitrogen demanded by ammonifying organisms, a minimum amount of nitrogen will be accumulated. However, when the readily available amount of energy material falls below the necessary ratio to nitrogen required by ammonifying organisms, the phenomena of ammonification will take place, although, if the energy material becomes too low, the ammonifying phenomena will be almost, if not entirely, lost.

As a result of this study, it is believed that ammonification is a doubtful criterion for measuring soil fertility.

Fission fungi which decompose urea and form nitrates, M. Düggeli (Naturio, Wehnschr., 30 (1915), No. 20, pp. 305-315).—This is a somewhat general discussion of the biology of some fission fungi and the chemical changes connected with their activities.

Enzym action in the marine algæ, A. R. Davis (Ann. Missouri Bot. Gard., 2 (1915), No. 4, pp. 771-836).—Difficulty having been experienced in demonstrating enzym action in Fucus vesiculosus (E. S. R., 30, p. 728), the investigation was extended to certain representative forms of the three great groups of the marine algæ in order to ascertain whether this apparent inactivity is characteristic of the algæ and to add to the knowledge of the general metabolism of the group.

The data obtained are thought to show that the number of enzyms in algae that can be isolated by standard methods is small. This seems to be true especially of the brown algae. The enzyms which were found in fresh or dried algal tissue include carbohydrases hydrolyzing the polysaccharids, starch, dextrin, glycogen, and laminarin, but not those hydrolyzing the several disaccharids employed as substrates; lipases acting upon neutral fats but not upon the esters of the lower fatty acids; proteinases; nucleases; oxidases and peroxidases; and catalases. Negative results were obtained from cellulase, cytase, maltase, lactase, sucrase, amidase, and esterase. The action of all the enzyms isolated was very slow.

An extensive bibliography is given.

On the action of pectase, N. G. Ball (Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1915), No. 28, pp. 349-357, fig. 1).—This is an attempt to study the action of pectase by observing the electrical conductivity of a solution of pectin obtained from roots of Daucus carota when acted upon by the enzym, and also by determining the change in viscosity.

It has been found that during the action of pectase on the solution of pectin the electrical conductivity of the solution remains constant, indicating the formation of a gel and not merely a very viscous liquid. The activity of the enzym is much greater at 14° C. than at 0°, as evidenced by changes in viscosity during coagulation. The viscosity was found to increase slowly at first, then more rapidly to a maximum, followed by a rapid decrease. Increase of electrolytes present lowered the maximum, while a decrease raised it. The decrease in viscosity is thought to be explainable by the action of the electrolytes in clumping together the particles of colloid forming the reticulum of the gel, so that a suspension is produced.

Osmotic pressures in plants.—IV, On the constituents and concentration of the sap in the conducting tracts, and on the circulation of carbohydrates

in plants, H. H. Dixon and W. R. G. Atkins (Sci. Proc. Roy. Dublin Soc., n. scr., 14 (1915), No. 31, pp. 374–392, figs. 6).—The authors, having followed up their previous work (E. S. R., 30, p. 523), give the results of observations on the sap drawn from the conducting tracts of several trees by centrifuging sections 10 cm. long by 2 cm. in diameter. The sap obtained by this method was neutral to litmus and clearer and much less concentrated than that obtained by pressure with consequent bursting of the cells.

Sugars were found at all times in the trees examined, being usually more plentiful than electrolytes. Sugars showed the greatest concentration in early spring, a dilution in spring and summer progressing to a minimum concentration in summer or autumn, then a rise in concentration, slow at first, culminating in the vernal maximum, which also coincided with the period of greatest root pressure and was simultaneous with or just preceded the opening of the leaf buds. These changes in concentration were due largely to changes in the transpiration rate.

The conveyance upward of carbohydrates, notably sucrose, is apparently a primary and continual function of the tracheæ. The sheath of wood parenchyma round the vessels functions as a gland to secrete carbohydrates into the rising transpiration stream. The relation of the medullary rays to these sheaths supports the view that they convey the carbohydrates from the bark to the glandular sheaths. The abundant presence of soluble carbohydrates in the wood sap of roots probably causes root pressure and bleeding by producing an osmotic pressure across the root cortex, which acts as a semipermeable membrane. The concentration of the carbohydrates is generally greater in the tracheæ of the stem than in those of the root, except during the summer. The electrolytes, however, are generally present in greater quantity in the root.

In general the vessels function, when water is abundant, to convey rapidly solutions of organic and inorganic substances to the leaves. The columns of tracheids may be supposed to afford a permanent channel for water and salts, and to a less degree, for the organic substances. Even in times of greatest drought, this is never put out of action.

A bibliography is given.

Osmotic pressures in plants.—V, Seasonal variations in the concentration of the cell sap of some deciduous and evergreen trees, H. H. Dixon and W. R. G. Atkins (Sci. Proc. Roy. Dublin Soc., n. scr., 14 (1915), No. 34, pp. 445-461, figs. 5).—The authors continue this series (see above) by reporting, with certain additions, the results of a revision, the necessity for which has been previously indicated (E. S. R., 29, p. 828). The sap for freezing-point determinations and conductivity measurements was pressed from tissues previously frozen in liquid air.

The authors state that the osmotic pressures in tissue and their variations are largely due respectively to dissolved carbohydrates and to fluctuations therein, but that electrolytes also play a part. A progressive average rise in the osmotic pressure has been found during the development and life of each organ examined. This is due in case of leaves to the accumulation of electrolytes with age, but in case of the only root examined, to carbohydrates.

The leaves of the two evergreens examined possessed higher osmotic pressure during the winter than during the summer months. The curve of seasonal variations in leaves of *Hedera helix* was alike for specimens growing either in a sunny or a shaded position, but on the whole the osmotic pressure was somewhat higher for the insolated leaves. The osmotic pressure of the root sap of *Hex aquifolium* rose from a minimum of 6 atmospheres in October to a maximum of 14 atmospheres in September.

No concentration of electrolytes with age was observed in these roots. The higher osmotic pressure in older roots is ascribed to increased carbohydrates. In each case the concentration of the total solutes of the sap expressed after freezing was greater than that of sap pressed from the same tissues untreated. The seasonal variations in concentration of the sap obtained by the two methods showed a remarkable similarity.

Some researches in experimental morphology.—I, On the change of the petiole into a stem by means of grafting, J. Doyle (Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1915), No. 33, pp. 405-444, pls. 7, figs. 3).—This is an account of attempts to ascertain whether the petiole of a plant can be made to function as a stem and to study any accompanying anatomical changes. The plants used were Pelargonium zonale meteor, Solanum richardi, S. balbesii, Sanchezia nobilis, and Phytolacca dioica. The technique, progress, and results of the work are described.

It is stated that the petiole, by grafting a sprout upon it, can be made to assume the functions of a stem. The properties of the stem, such as long life duration, indefinitely active cambium, interfascicular cambium linking up bundles, peridermium development, and considerable secondary thickening, all appear in the petiole. It is held that the causes of the secondary thickening lie in the removal of correlational influences, increased mechanical strain, and some influence connected with foliar development, supposedly bound up in some way with the water economy, particularly transpiration.

A bibliography is appended.

An investigation of the causes of automatic movements in succulent plants, Edith B. Shreve (*Plant World*, 18 (1915), Nos. 11, pp. 297-312, figs. 6; 12, pp. 331-343, figs. 5).—As the result of a study carried out on a number of cacti it is claimed that the seasonal movements observed are correlated with turgidity changes, as were also daily movements which were studied in some detail. Other influences acting in the case of short period movement, through intermediate processes, are temperature, light intensity, evaporative power of the air, and water content of the soil and plant tissue.

It is claimed that the form of the adult cactus plant and the position of its branches are determined by the water relations existing during the period of growth and secondary thickening of its various parts, and not by any peculiarities in its growing point and in its mode of initiating branches.

The relation of evaporation and soil moisture to plant succession in a ravine, F. T. Ullrich (Bul. Ill. State Lab. Nat. Hist., 12 (1915), Art. 1, pp. 16, pls. 19).—The author gives an account, with interpretation and discussion of results, of a study during the summer of 1913 on the evaporation rates in different portions of a ravine which is described. The data obtained are claimed to show clearly that the differences in the rates of evaporation at the various stations are sufficient to indicate that the atmospheric conditions are effective factors in causing plant succession in a ravine.

A study of the relation of transpiration to the size and number of stomata, W. L. C. MUENCHER (Amer. Jour. Bot., 2 (1915), No. 9, pp. 487-504, figs. 3).—From the determinations made by the methods described upon a number of plants, the author concludes that the number of stomata per unit of leaf surface varies simultaneously with the length of the pore for the several species, so that two variables are to be considered. No correlation was found between the amount of transpiration and the length of the pore of one stoma or the number of stomata per unit of leaf surface in the different species investigated. No constant relation was found between the amount of water lost and the number of linear units of stomatal pore, that is, the number of stomata per unit

of leaf surface multiplied by the length of the average pore in the various species studied.

It is thought probable, therefore, that the amount of transpiration is not governed entirely by stomatal regulation, and that the variations in the amount of water loss in different species can not be accounted for by the size and number of stomata, but may be explained perhaps by a complex of several factors.

A short bibliography is appended.

The utilization by plants of acids and bases from different nitrates, B. M. Arnoldi (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 407-430).—It is stated that nitric acid is taken up from its salts more rapidly than are the bases potassium, sodium, calcium, or ammonium. The energy of absorption varies, however, with the different metals. Nitrates were in part utilized in darkness by the plant.

The influence of alkaline reactions shown by solutions after repeated use, M. A. Starodubowa (Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 392-406).—It was found, contrary to expectation, that in case of oat and wheat plantlets permitted to sprout and grow for not over two weeks in a 0.2 per cent solution of sodium nitrate, the seedlings showed some actual increase of vigor in spite of the increased alkalinity until the eighth successive series had been grown in the medium. This, it is thought, may indicate that the supposed excretion of harmful substances from such sprouting plants does not begin in these plants before they are two weeks old.

Toxicity of galactose for certain of the higher plants, L. Knudson (Ann. Missouri Bot. Gard., 2 (1915), No. 4, pp. 659-666, pl. 1).—Experiments with vetch having shown marked injury following the use of galactose in a nutrient medium, tests were made on other leguminous plants to determine whether or not the effect of the galactose is consistent.

It was found that, while other sugars acted beneficially, galactose showed an injurious action on *Vicia villosa* and *Pisum sativum*. It does not appear to be toxic to fungi, since several of these were found growing in cultures which had become contaminated therewith. The character of the injury and the method of action by galactose have not yet been determined. It apparently kills the cells with which it comes in contact. Glucose appears to neutralize the toxicity of galactose in some way not yet understood.

Fumigation experiments to determine the effect of highly diluted sulphur dioxid on a growing grain crop, A. E. Wells (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 213-307, pls. 13, fig. 1).—This is the author's report to the Selby Smelter Commission.

The tests were carried out with barley in actual cultivation, an improved method of sulphur dioxid gas delivery being employed which reproduced, as regards maintenance of uniformity, actual outside conditions as nearly as possible. It is stated that, next to concentration of sulphur dioxid, duration of exposure thereto is the chief element in the causation of injury, and that the effects of the time factor are not materially altered when the applications are made at intervals, provided these are short. The humidity of the atmosphere is also a strong determinative factor, exceeding in importance temperature changes and the influence of sunlight and shade.

A preliminary account of a new œdanometer for measuring the expansive force of single seeds, or similar small bodies, when wetted, J. B. BUTLER and J. M. SHERIDAN (Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1915), No. 35, pp. 462–480, figs. 4).—It is claimed for this device that it measures the force rather than the volume of the swelling. The several forms are designed to measure pressures due to the swelling of single seeds as well as of quantities sufficient to fill considerable space.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from October 1 to December 31, 1913 (U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 37 (1916), pp. 95, pls. 6).—Notes are given of seeds and plants imported from various sources from October 1 to December 31, 1913, about 700 numbers being included. These were largely obtained from an expedition to Brazil made by P. H. Dorsett, A. D. Shamel, and W. Popenoe, a collection by S. C. Mason in Egypt and Nubia, and collections by F. N. Meyer in China.

International catalogue of scientific literature. M—Botany (Internat. Cat. Sci. Lit., 11 (1914), pp. VIII+856).—The literature herein catalogued is said to be mainly that of 1911, but to include some entries dated 1912 and portions of the literature of 1901 to 1910, the index slips for which were received too late for inclusion in previous volumes (E. S. R., 29, p. 327).

International catalogue of scientific literature. M—Botany (Internat. Cat. Sci. Lit., 12 (1915), pp. VIII+835).—The literature indexed herein is mainly that of 1912 and 1913, but includes also material received too late for insertion in previous issues.

FIELD CROPS.

The influence of relative area in intertilled and other classes of crops on crop yield, D. A. Brodle (U. S. Dept. Agr., Office Sec. Circ. 57 (1916), pp. 8, fig. 1).—A report is presented on studies as to the relation of the type of farming to the maintenance of crop yield made in 1914 and 1915 on 240 farms in Chester County, Pa., and on 303 farms in Central Illinios. The labor income was used as the measure of efficiency in producing profits, and the crop index or percentage relation of the crop yields of a particular farm to the average crop yields of all the farms in the community as the measure of efficiency in maintaining crop yield. Use was also made of two other studies furnishing data on this subject, one covering 377 Chester County, Pa., farms, and the other, 300 farms in Lenawee County, Mich. The relation of different groups of crops to crop yield is shown in tables and discussed.

For the purpose of this study the farm crops were divided into intertilled, annual not intertilled, and perennial crops. The results indicated that in all the districts so far studied an optimum percentage of the crop area of the farm may be devoted to a single class of crops and maximum yields maintained. Under the rather intensive types of farming studied in Pennsylvania and Michigan and under the more extensive type practiced in Central Illinois, the optimum area of intertilled crops in each case was found to fall within 5 per cent of each other, the range being about from 32 to 36 per cent. It was further indicated that when more than this percentage of area is devoted to a single class of crops, yields decrease even where there is an increase in the number of live stock per acre.

The area devoted to small grain in the Pennsylvania area is so small that it is regarded as either not directly affecting crop yield or that its influence is completely masked by the effect of the amount of manure available. The optimum percentage area for perennial grass, which is mainly timothy and clover in Chester County, Pa., was about 36 per cent of the crop area of the farm.

A cropping system constructed from data brought out in a survey made in 1912 was found to correspond very closely to the practice of those farmers on the one hand who maintain high yields and with those on the other hand who made the highest profits. Taking the data secured in Chester County, it is stated that with the allowance of about 10 per cent of the crop area of various crops not in the rotation such as garden, orchard, soiling crops, and the like,

there should be in the cropping system about 36 per cent of the crop area in intertilled crops, about 36 per cent in perennial grass, and the remaining 18 per cent in annual crops not intertilled.

Contributions to agronomic terminology, I, C. R. Ball and C. V. Piper (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 1-9).—A paper discussing the need and value of a clear and definite terminology in agronomy, and presenting and defining 35 terms relating to the operation of seeding and setting and 88 terms relating to the meadow and pasture industry.

Progressive agriculture, H. W. Campbell (*Lincoln, Nebr.: Author, 1916, pp. 155, figs. 49*).—A popular treatise on the culture of different crops and the methods of soil management in the semi-arid regions of the United States.

Experiments with field crops, C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 27, 28).—In these experiments three uniform ½-acre plats were differently prepared in September, 1912. One plat was plowed and then subsoiled, the second or middle plat was prepared by boring holes 30 to 36 in. deep a rod apart and discharging ½-lb. stick of dynamite in each hole, while the third plat was plowed in the usual way. In 1913, the entire field was planted to potatoes, in 1914 to corn, and in 1915 to rape, the preparation being uniform over the three plats. There were no appreciable differences in the crop on the different plats, and this result is taken as indicating that under the soil conditions at Highmoor Farm no advantage results from the use of dynamite for loosening soil for field crops.

[The Woburn field experiments, 1914], J. A. VOELCKER (Jour. Roy. Agr. Soc. England, 75 (1914), pp. 286-306).—These experiments are a continuation of work previously noted (E. S. R., 27, p. 831). The year 1914 was the thirty-eighth of the continuous growing of wheat and barley on the same land with the annual or biennial application of different kinds, amounts, and combinations of fertilizers for the different plats. The season was marked by very dry weather from March to harvest time. The yields of wheat were much below the average, those of barley were better, and those of oats were poor.

In the wheat experiment the highest yield, 19.1 bu. per acre, was secured on the plat receiving 3 cwt. of superphosphate, ½ cwt. of sulphate of potash, and 25 lbs. of ammonia in the form of the sulphate. The plat receiving 100 lbs. of ammonia in barnyard manure ranked next with a yield of 11.5 bu., and the one receiving 25 lbs. of ammonia in rape dust stood third with 11.2 bu. per acre. In general the results seemed to indicate that the nitrate of soda plats are failing as a rule and that the land on which this work is conducted is more in need of phosphates than of potash. The barnyard manure plat stood first in the yield of straw with 15 cwt. and 8 lbs. per acre. The results of a variety test were decidedly in favor of Square Head Master as compared with Svalöf and Tystofte, Swedish and Danish wheats, respectively. The use of 4 tons of magnesia per acre apparently gave an increase in the nitrogen content of the wheat but had no influence on the baking quality.

In the barley experiments the barnyard manure plat gave the largest yield, 24.6 bu. per acre, being followed by the plat receiving 3 cwt. of superphosphate and 25 lbs. of ammonia as nitrate of soda per acre with 24.5 bu. The plat receiving 3 cwt. of superphosphate, ½ cwt. of sulphate of potash, and 25 lbs. of ammonia in the form of sulphate per acre, 2 tons of lime having been applied in 1897 and repeated in 1912, ranked third with a yield of 24.3 bu. Sulphate of ammonia used alone or with minerals but without lime gave no crop in any case. A test of varieties showed Tystofte Prentice and Archer about equal in yield and both ranking higher than Syalöf Primus. In quality of grain Tystofte Prentice stood a little higher than Archer.

Mangolds following wheat which had been treated at the rate of 2 tons of magnesia per acre appeared to show a slight residual effect of this application,

In a variety test of oats the Swedish variety Svalöf Victory yielded 37.4 bu. and Banner, a Canadian variety, ranked next with 34.5 bu. per acre. Among four varieties of flax La Plata produced the highest yield of seed. The results of a comparison of Pacey, Dutch, and Italian rye-grass were in favor of Italian rye-grass in two years out of three. A grass mixture with ordinary white clover gave a heavier yield of hay than the same mixture with wild white clover, but the wild white clover proved more promising for pasturage.

A test of varieties of alfalfa resulted in favor of the Russian variety, the Canadian ranking next, with Provence but slightly inferior. American (Arizona) and Turkestan gave the lowest yield.

In grass experiments the best results in improving old pasture were obtained on a plat which had been limed at intervals, the last application having been made in 1909, and which had received superphosphate and sulphate of potash in 1913. Of different kinds of lime, magnesium lime proved the least effective. Ground lime seemed to have given better results than lump lime.

[Field experiments at the Cuttack Experiment Station, 1914–15], G. SHERRARD (Rpt. Dept. Agr. Bihar and Orissa, 1914–15, pp. 45–51).—Fertilizer and variety tests with rice, and culture and seed selection experiments are briefly described.

The method of transplanting about two rice seedlings 9 or 10 in, apart compared with the practice of transplanting eight or ten seedlings 5 or 6 in, apart gave better yields of grain in each of three years, but the yield of straw was generally in favor of the thicker planting. Experiments undertaken to determine the best rate for broadcasting rice indicated that a saving of from about 18 to 36 lbs. of seed-rice per acre as compared with the general practice can be made without reducing the yields. In the experiment reported, about 27 lbs. of seed-rice per acre on well-prepared ground and omitting the after-plowing gave higher yields of grain in every case than larger quantities of seed per acre together with the customary after-plowing.

In an experiment on the production of jute fiber and rice when grown in rotation in the same year with about 16,000 lbs. of cow manure applied to the jute, an average yield of 843 lbs. of jute fiber and 2,153 lbs. of rice grain and 3,027 lbs. of straw were secured on irrigated land during the four years 1912–1915, inclusive.

[Field experiments], S. N. Sil (Rpt. Dept. Agr. Bihar and Orissa, 1914-15, pp. 11-29).—The results of experiments conducted at the Sabour Agricultural College during the year ending June 30, 1915, are reported.

Among other results constant cultivation of fallow during hot weather as compared with no cultivation and the use of about 8,000 lbs. barnyard manure per acre gave increased yields of wheat in every test.

Rice seedlings grown in moist seed beds proved more satisfactory than those produced under dry seed-bed methods. Seedlings two months old when transplanted gave better results than younger or older seedlings. Spacing the plants 6 or 9 in, apart gave much better results than spacing either 12 or 18 in. Green manuring of rice lands for three successive years also proved beneficial. An experiment in which from 1 to 40 rice seedlings were planted per hole showed that 1 or 2 selected and 4 or 6 unselected seedlings per hole appeared to be the economic limit in transplanting. Root-pruning appeared to stimulate the growth of rice seedlings. In a fertilizer test the use in alternate years of about 250 lbs. of bone meal per acre proved more effective than the use of about 415 lbs.

Rahar (Cajanus indicus) sown in June produced heavier yields than sowings made in July.

[Field experiments at Dumraon Experiment Station, 1914–15], G. SHERBARD (Rpt. Dept. Agr. Bihar and Orissa, 1914–15, pp. 38–44).—The different lines of work pursued during the year are briefly described. The results of manurial tests with rice showed that an annual application of about 400 lbs. of cow manure per acre for 4 years was distinctly profitable as compared with other treatments, and gave better returns even than the use of double the quantity.

[Experiment station work in New South Wales, 1914–15] (Rpt. Dept. Agr. N. S. Wales, 1915, pp. 132, pls. 12).—Brief general reports are presented on the experimental work and other activities of the Bathurst, Berry, Coonamble, Cowra, Glen Innes, Grafton, Trangie, Wagga, Wollongbar, and Yanco experiment farms, and a number of demonstration farms. Experiments conducted at Hawkesbury Agricultural College, Lambrigg, and Howlong are also briefly noted.

In a test of 13 varieties of oats at Cowra, a cross between White Ligowo and Algerian ranked first in yield with about 36 bu. per acre, followed by Sunrise producing only a few pounds less. Bathurst No. 4 and Ruakura Rust Resistant also gave promising yields. At the Hawkesbury Agricultural College Cleveland and Warren wheats succeeded best and Ruakura oats was the most rust-resistant and gave the highest yield.

The outstanding feature of the ear-to-row tests in corn-breeding work at the various farms was the variation in yield between the different rows. In every test the highest yielding row produced more than twice as much as the lowest yielding row. It was also found that some of the best yielding rows were almost uniform throughout in type. A cross between Hickory King and Boone County White corn is described as having the small cob and hard, medium-large grain of Hickory King but the deep, wedge-shaped kernels of Boone County White.

In selection experiments at Grafton with Leaming corn the highest yielding row gave 70.2 bu. per acre and the lowest 26.7. The average of 20 ears selected from the crib was 45.5 bu., and the average of 16 field-selected ears 52.1 bu. per acre. No advantage was derived from selecting for two ears per stalk, and ears selected from stalks thick at the base yielded better on an average than those from thin stalks. Ears selected from plants with suckers, especially if these also bore small ears, yielded higher in nearly every case than ears from suckerless stalks. Ears drooping at maturity generally out-yielded those erect at maturity. A correlation appeared to exist between medium red color of the kernels and good type of ear.

Results in experiments with Improved Yellow Dent showed that the highest yields were obtained from ears selected from short or medium tall stalks. Ears selected from very tall stalks gave low yields in almost every case, and ears placed low on the stalk gave distinctly higher yields than ears high on the stalk. Ears drooping at maturity yielded 9 per cent higher than erect ears.

Results secured in breeding work with sorghum indicated a correlation of earliness and dwarf stature with grain production, and lateness and tall fodder growth with low seed production. The yield of individual rows ranged from 24 to 9½ tons of fodder per acre, and from 1.25 to 29.6 bu. of seed per acre. The best row of a dual purpose strain yielded at the rate of 5.3 tons of fodder and 24.6 bu. of seed per acre.

[Effect of inoculation material on the development of wheat, rye, oats, and barley] (North Dakota Sta. Rpt. 1915, pt. 1, pp. 15, 16).—Seed of wheat, oats, rye, and barley was treated with an inoculation material for which it was

claimed that similar results to those secured from the inoculation of the soil for leguminous crops could be obtained. Treated and untreated seed was sown on plats of equal size and condition but no material difference between the plats sown with treated and untreated seed was visible during any part of the growing season. It was concluded that so far as the soil was concerned the application had no value.

Forage crops in central Washington, M. A. McCall (Washington Sta. Bul. 128 (1916), pp. 3-11, figs. 9).—Brief notes are given on the results of cooperative trials with forage crops, including corn, sorghum, alfalfa, sweet clover, field peas, rye, and wheat.

Soy bean and cowpea, F. H. HALL (New York State Sta. Circ. 45 (1915), pp. 6).—Notes on the general character of these crops, their culture, uses, and value, are presented with special reference to conditions obtaining in the State of New York. It is reported that in 1915 only did the method of planting soy beans and corn together in the same row produce satisfactory growth of soybean forage at the station, and that even then the seeds were far from mature.

Comtesse and Sarah, new French varieties of barley, L. Blaringhem (Assoc. Franç. Avanc. Sci., Compt. Rend., 43 (1914), pp. 971-974, fig. 1).—The two varieties of barley described resulted from work entered upon in 1903 for the purpose of improving varieties to meet the requirements of the brewery as well as of the farm. Both varieties belong to the species Hordeum distichum nutans and are of pure line breeding. Comtesse yielded from 32.1 to 43.6 bu. per acre in 1912 and from 28.7 to 34.4 bu. in 1913 on soils of medium fertility. The variety Sarah yielded from 37 to 44.5 bu. per acre in the Champagne region and from 40.1 to 43.5 bu. on calcareous soils in the vicinity of Saumur.

Alexandrian clover, A. CARRANTE (Agr. Colon [Italy], 9 (1915), Nos. 8, pp. 467-480; 9, pp. 546-556; 10, pp. 583-619; 11, 646-680; 12, pp. 725-756; pls. 19).— An article discussing the subject under the following heads: Origin and botanical characters, agronomic and biological characters in their relation to the culture of the plant, varietics, culture in Egypt and other countries, climatic and soil requirements, cultivation of the crop, cultivation under irrigation, culture in crop mixtures, utilization of the forage and its feeding value, fertilizing value, adverse conditions and parasites, relation to farm management, and comparison with other leguminous crops.

[Experiments with oats], C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 4-14).—A fertilizer test indicated that the phosphoric acid is not a controlling factor in the yield of oats under Aroostook farm conditions.

Fifteen varieties of oats tested at Aroostook Farm in 1915 gave an average yield of 60.1 bu, of grain and 2,285 lbs, of straw per acre. The two leading varieties, Early Pearl and Siberian, yielded 73.7 and 70.6 bu, per acre, respectively, and were the two latest maturing varieties in the list. Kherson, a variety ripening about 10 days before the varieties of medium maturity, ranked third with a yield of 67.6 bu, per acre.

A similar test at Highmoor Farm with 11 commercial varieties resulted in an average yield of 73.9 bu, of grain and 3,384 lbs. of straw per acre. Early Pearl ranked first with 86.6 bu, of grain, Banner second with 83.3 bu,, and Minnesota No. 26 third with 81.7 bu, per acre. These varieties have been tested for three years and the average results place Early Pearl first with 84.6 bu, followed by Minnesota No. 26 with 83.5, Gold Rain with 81.2, and Banner with 80.3 bu, per acre.

In a test in 1915 of 12 pure lines of oats originated at Highmoor Farm an average yield of 79.1 bu, of grain and 3,621 lbs, of straw per acre was secured. The leading strains were Maine No. 340 with 82.8 bu, Maine No. 355 with 82.2, Maine No. 281 with 81.3, and Maine No. 247 with 80.2 bu, per acre. The average

results for three years show a yield of 82.8 bu. per acre and a range from 79.9 to 88.5 bu., the strain ranking first being Maine No. 340.

An experiment of seeding oats at the rate of 8, 10, 12, 14, 16, and 20 pk. per acre gave results decidedly in favor of the seeding with 14 pk., and indicated that when the crop is seeded with 3 or 3½ bu. per acre the yield is likely to be as great as when seeded with 4 or 5 bu. The experiment was planned to be repeated in 1916.

Oats in Washington, E. G. Schafer and E. F. Gaines (Washington Sta. Bul. 129 (1916), pp. 3-13, figs. 3).—This bulletin describes 16 varieties of oats and reports the results of tests of a list of varieties in the nursery and the field.

Regarding the average yield of all the varieties in the nursery test as 100, the comparative yields ranged from 121.4 for Sparrowbill to 51.5 for Chinese Hulless. In the field tests Abundance, Banner, Swedish Select, and Sixty Day led in yield. Averaging the results of the field and nursery tests the leading varieties, given in decreasing order of yield, were Abundance, Banner, Sparrowbill, Swedish Select, and Sixty Day, all of which gave a yield above the average of the eight varieties in the tests.

[Experiments with potatoes], C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 16-27).—An experiment is reported on the effect of omitting potash from the fertilizer application in growing potatoes. The four different mixtures used contained 4 per cent of nitrogen, of which one-third was in the form of nitrate of soda and 8 per cent of available phosphoric acid. The first plat in each of the two series received no potash, the second 2 per cent, the third 5 per cent, and the fourth 8 per cent. In each case the fertilizer was applied at the time of planting at the rate of 1,500 lbs. per acre. The average yield on the two plats receiving no potash was 302 bu. as compared with 320 bu. on those receiving 2 per cent, 320 bu. on those receiving 5 per cent, and 331 bu. on those receiving 8 per cent of potash. It is concluded that while the results from the use of the larger amounts of potash indicate that potash may be expected to increase the yield of potatoes in Aroostook County, they also indicate that a profitable yield can be obtained without its addition for at least one year.

In a comparison of different methods of applying the fertilizer in potato culture at Aroostook Farm, 1,500 lbs. per acre was used of a fertilizer carrying 4 per cent nitrogen, 8 per cent available phosphoric acid, and 7 per cent water-soluble potash. One-third of the nitrogen was in the form of nitrate of soda and the remainder was high-grade organic nitrogen. The entire quantity was applied in the planter or broadcast, or 1,000 lbs. was applied in the planter or broadcast and 500 lbs. given when the crop was up. The average results of two years show that there is little to choose between the methods compared, and the experiment is to be repeated for further data.

In a comparison of sulphate of ammonia and nitrate of soda as a source of nitrogen in potato fertilizers, the results for two years show that the sulphate of ammonia plats gave somewhat larger yields than the nitrate of soda plats. The organic nitrogen did not appear to be as completely available as the two other forms,

The culture of the peanut, J. M. DE SOUZA (*Rio de Janeiro: Min. Agr. Indus. e Com., 1915, pp. 3-13*).—The culture of the peanut and its uses are briefly described, and in this connection notes are given on the origin, history, synonomy, geographical distribution, and climatic requirements of the plant.

The botanical origin of the cultivated varieties of rice, O. ROEHRICH (Assoc. Franç. Avanc. Sci., Compt. Rend., 43 (1914), pp. 479-487).—Historical notes on the development and distribution of rice culture are given, together with botanical descriptions of Oriza latifolia, O. brachyantha, O. breviligulata, O. longistaminata, and O. sativa.

Varieties of soy beans, F. A. Welton (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 99-101).—Notes are given on the culture of soy beans and the results of a 4-year test of 25 varieties are tabulated.

Of 6 early varieties or those ripening on or before September 27, Chestnut and Ito San 17268 had an average yield exceeding 27 bu. per acre. The best yielding varieties in the list with an average yield above 28 bu. per acre were Ohio 7486, Ohio 9016, and Ohio 9110, varieties maturing from September 28 to October 6. Of the late varieties or those maturing on or after October 7, Ohlo 7491 and Ohio 9035 ranked highest with 26.28 and 25.58 bu. per acre, respectively. For the production of hay, Cloud, Ohio 9035, Sable, Taha, Auburn, Ebony, Medium Green, and Shingto, and for silage, varieties of the type of the Medium Green gave promising results. Plans for cooperative work in testing promising strains isolated by the station are briefly outlined.

Variety tests with sugar beets (*Ztschr. Zuckerindus. Böhmen, 40* (1916), No. 4, pp. 155-170).—These tests were conducted in triplicate at each of four different points by the sugar industry association of Bohemia, and the samples studied were made up of 50 beets from each plat.

The average yields of varieties grown in 1915 were as follows: Dippe 33,995, Zapotil 33,549, Schreiber 33,665, Dobrovic 33,585, Rabbethge and Giesecke 33,290, Kuhn 36,048, Mandelik 33,133, and Dobrovic "average," which differed from Dobrovic only in the seed sample, which was made up by the growers from seed grown in their several fields, 33,754 lbs. per acre. The corresponding sugar contents were 19.53, 19.54, 19.31, 20.02, 19.51, 19.37, 19.58, and 19.94 per cent.

A comparative study of the weeds of central Iowa, northern Minnesota, and Wisconsin, L. H. Pammel (*Proc. Iowa Acad. Sci.*, 22 (1915), pp. 57-59).—A table is given showing the occurrence or nonocurrence of a list of weeds at Ames, Iowa; St. Paul, Brainerd, Cass Lake, and Duluth, Minn.; or St. Croix Falls, Wis.

[Eradication of quack grass] (North Dakota Sta. Rpt. 1915, pt. 1, p. 16).—Flake potash was applied in different amounts up to 16,000 lbs. per acre in direct contact with the grass. The heaviest application seemed strong enough to kill the quack grass on the surface of the ground, but it did not prevent the final growth of the grass from the lower root stalks.

HORTICULTURE.

[Report of horticultural investigations] (Georgia Sta. Rpt. 1915, pp. 9-12).—A brief statement of progress made in various horticultural projects, under the direction of H. P. Stuckey, during the year.

In breeding work with tomatoes it was found that first and second generation plants from the crosses between the red cherry tomato and Greater Baltimore, a large commercial variety, gave fruit resistant to the blossom-end rot and in size intermediate between the fruit of the two parents. Plants resulting from seed taken from diseased tomatoes of the Globe variety produced fruit more susceptible to blossom-end rot than did plants grown from seed taken from sound fruit.

A selection from the third generation progeny of a cross between the Georgia collard and the Charlestown Wakefield cabbage has given a stocky, compact plant, intermediate between the parent types and apparently resistant to disease.

In the spring of 1912 one acre was set to apple trees, every other row being stock infected with crown gall and every other row being set to sound stock. Measurements at the end of the season 1915 show that the sound stock

had made a little better growth than the crown-gall infected stock. A collection of varieties of pears was set out in the spring of 1912 to determine the influence of fertilizers and cultural methods on the development and spread of the pear blight. Of these varieties a pear of the Garber type, belonging to the *Pyrus sinesis* group and secured from the eastern section of South Carolina, was found to be practically immune to the blight. This pear is slightly superior to the Kieffer in quality.

Observations made on the flowers of a number of Elberta peach seedlings confirmed previous observations reported by Hedrick (E. S. R., 29, p. 424) with reference to the relation of the color of the inside of the corolla cup and the color of the flesh of the peach. Deep orange corolla cups gave yellow flesh peaches; light yellow or green corolla cups gave green or white flesh peaches.

An investigation of the cause of partial or entire self-sterility existing among certain varieties of pecans has shown that the varieties can be divided into two distinct groups based on the floral character of the catkins of the staminate flowers. The two most important differences between these two groups from an economic standpoint are the difference in the viability of the pollen and the difference between the time the pollen is shed and the time the pistillate flower becomes receptive. The pollen of one group was found to be approximately three times as viable as that of the other group and the pollen was shed at approximately the same time that the pistillate flowers became receptive. In the other group the difference in time between the shedding of the pollen and the receptive stage of the pistillate flower ranged from 6 to 13 days. These observations indicate that a certain number of early blooming varieties should be interplanted with those varieties in which the pollen is late in developing.

A large number of crosses between the black and white fruiting varieties of Rotundifolia grapes showed that black is dominant to white and that white is a pure recessive, thus indicating that white or light fruiting vines may be produced by pollinating the flowers of Scuppernong vines with pollen from white male vines. Studies thus far made of the microspore development of *Vitis rotundifolia* in order to ascertain the cause of self-sterility in these grapes have shown that the microspores functioned normally in both male and female through the tetrad stage. Following this stage the pollen from the self-sterile varieties shows signs of degeneration.

A B C of vegetable gardening, E. E. Rexford (New York and London: Harper & Bros., 1916, pp. 116).—A popular treatise on the culture of vegetables and small fruits.

Spraying programs for the small home orchard and fruit garden, H. A. Gossard and W. J. Green (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 103-107).—This comprises abridged spraying programs for the treatment of orchard and small fruits. The programs are prepared with special reference to the owners of small orchards.

Spray formulas for the town lot, P. Thayer (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 114-116).—The author has here perfected a set of spray formulas adapted for use in the small fruit garden where only a few trees and bushes are to be sprayed. Wherever possible measures are given permitting of the ready preparation of small amounts of spray materials.

Culture of cabbage, J. W. Wellington (New York State Sta. Circ. 48 (1916), pp. 5).—This circular contains concise directions for growing cabbage, including instructions for the control of diseases and insect pests and a list of the more important varieties.

New or noteworthy fruits, IV, U. P. Hedrick (New York State Sta. Bul. 414 (1916), pp. 3-10, pls. 5).—In continuation of a previous bulletin (E. S. R., 33, p. 238) the author describes the best recent fruit introductions as tested

on the station grounds. The varieties here described include the Perfect apple, Rochester peach, Reine Hortense cherry, the Empire State grape, and Herbert raspberry.

Fifteenth report of the Woburn Experimental Fruit Farm, Duke of Bedford and S. U. Pickering (Woburn Expt. Fruit Farm Rpt., 15 (1916), pp. 83).—
This comprises a progress report on a number of long-continued investigations with fruit trees and shrubs and other trees.

Among other points being investigated, it has been sought to determine whether apple trees have a tendency to produce alternate light and heavy crops. One experiment favoring alternate cropping was recorded in a previous report (E. S. R., 17, p. 559). Subsequent experiments have led to the conclusion that the tendency toward alternate cropping is very feeble and that there is at the same time an equally potent tendency to consecutive cropping, that is, a tree bearing particularly well or badly during one season will probably do the same in the succeeding season. It is believed that the chief factor in determining good or poor bearing is the atmospheric conditions rather than any innate tendency of the individual tree to either alternate or consecutive fruiting. In the experiments conducted at Woburn the principal factor influencing bearing has been spring frosts.

Several series of experiments were made to ascertain the distribution of new rootlets forming on trees after transplantation. In the case of apples less than half of the new rootlets originated within the last half inch of the old roots which had been trimmed before planting, whereas with currants and gooseberries more than half originated from this half inch. Roots originating from the stems were found to be on the average 20 per cent greater in stoutness than that of roots forming elsewhere. This result explains the habit of deeply planted free-rooting stocks of flourishing better after a time than similar stocks planted at the ordinary depth. With reference to the effect of trimming the roots of the tree at the time of transplanting on the subsequent formation of new roots, the results showed considerable variation in different seasons and with different plants. The general conclusion is reached that trimming is of no importance.

Further tests of orthodox and careless methods of planting trees (E. S. R., 20, p. 1034) have continued to show no bad effects. In the case of two series of experiments in which the ground was rammed around the trees after the trees were planted the advantage gained by this procedure persisted throughout the succeeding seven or eight years. In one instance, however, where the trees were planted in a type of clay unsuited for fruit culture ramming proved to be very deleterious, the soil around the roots developing sulphuretted hydrogen owing to the absence of aeration. Ramming experiments conducted with 1,400 forest trees of various sorts resulted in only a slightly greater growth for the rammed trees, but the subsequent mortality among the rammed trees was only half as great as among those not rammed.

Experiments were undertaken to ascertain whether apple trees in a heavy soil suffered less from canker if they were planted higher than usual. Certain varieties subject to this disease were planted at the usual depth and also with their roots flush with the surface of the ground. Observations over a period of ten years show that the high-planted trees have not flourished quite so well as the others. No relation between their behavior in successive years and the rainfall was observed. The high-planted trees have suffered somewhat less from the attack of canker.

Experiments dealing with the cutting back of the branches of trees at the time of transplanting have shown that such cutting back may be delayed up to any time before active growth begins without any injury to the trees.

If delayed until the summer the effect is very deleterious and remains in evidence for many years afterwards. If the operation can not be done before summer, it is recommended that it be deferred until the succeeding winter. When this cutting back is deferred to the end of the first year and is followed by excessive root growth very strong branch growth subsequently occurs, at least during one season. The tree often continues this growth and does not come into proper bearing until several years later than similar trees which have been cut back at the time of transplanting.

Evidence was obtained as to the importance of trees being exposed as little as possible during the removal from the nursery to the plantation. Trees which were left in a shed for four days after being lifted and before being planted suffered to the extent of about 50 per cent in their subsequent growth. The authors attribute the less satisfactory results from spring planting as compared to early winter planting to the exposure to the more prevalent drying winds in the spring.

Experiments dealing with the effect of branch pruning on fruit production were continued (E. S. R., 19, p. 142), the results previously noted being confirmed and extended. The results show in general that to secure the heaviest crops the pruning should be just sufficient to develop healthy, well-formed trees.

Winter washes tried at Wisley, 1914–15, H. M. Lefroy (Jour. Roy. Hort. Soc., 41 (1915), No. 2, pp. 230–233).—The author reports tests of a number of winter washes used on apple and plum trees. The washes were studied with special reference to solubility in or miscibility with water, corrosiveness as affecting the rubber tubing, etc., effect on workers or their clothes, wetting power, cost, and general effectiveness of the wash.

Experiment in setting apple trees, C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 28-30).—A number of Baldwin apple trees were planted in 1913, part of the trees being set in the usual way by digging holes in the spring with a spade. The remainder of the trees were planted in the spring in soil that had been loosened with dynamite the previous fall. Practically no difference in growth was observed between the two lots of trees in 1913 and in 1914. In the spring of 1915, however, it was found that about 39 per cent of the trees planted in the holes previously dynamited were either winterkilled or badly injured as compared with only 8 per cent of those planted in the usual way. No general conclusion is drawn from these data. For the soil in question, however, which is a moderately heavy, reddish loam underlain with a very difficultly penetrable subsoil, it appears that dynamiting is of no value in setting trees.

Fertilizer experiments on apple trees at Highmoor Farm, C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 2-4).—In connection with some fertilizer experiments with apple trees conducted at the Highmoor Farm for several years a test is being made of highly nitrogenous fertilizers as a means of forcing trees into bearing. Each year the orchards as a whole have received a commercial fertilizer carrying 4 per cent nitrogen, 8 per cent available phosphoric acid, and 7 per cent potash at the rate of 1,000 lbs. per acre. In the excess nitrogen plats the trees have received in addition nitrate of soda at the rate of 100 lbs. per acre. Thus far no differences that could be attributed to the additional nitrogen in the fertilizers have been noticed.

An experiment was begun in 1912 with some 400 trees which had received all the above noted fertilizer treatment for three years. The trees were divided into 3 plats, one of which received no fertilizer, the second 500 lbs. per acre annually of the 4:8:7 formula, and the third of which received 1,000 lbs. per acre of the 4:8:7 formula. Observations to date failed to show any differences even in appearance between the fully fertilized, partially fertilized, and unfertilized trees. The actual yields in fruit, however, in 1914 and in 1915,

which were fair crop years, were larger on the fertilized plats. The yields for 1915 showed an increase consistent with the amount of fertilizer used.

The experiment is to be continued for a number of years before definite conclusions are drawn.

Field experiments in spraying apple orchards, B. S. Pickett et al. (Illinois Sta. Bul. 185 (1916), pp. 49-212, figs. 22).—This bulletin comprises reports on a number of field experiments conducted in the leading orchard sections of Illi-The experiments were undertaken for the purpose of coordinating the results of earlier investigations into general systems of spraying, the attempt being made to evolve methods of practice which would be practical from a commercial standpoint. The following work is reported: Spraying experiments in 1910, 1911, and 1912 at Neoga, Cumberland County, by O. S. Watkins (pp. 58-103); spraying experiments in 1912 at Flora, Clay County, by W. A. Ruth (pp. 104-117); spraying experiments in 1909 at Griggsville, Pike County, in 1910 and in 1911 at Centralia, Marion County, and in 1912 at Anna, Union County, by L. E. Foglesong (pp. 118-155); spraying experiments in 1911 and in 1912 at Griggsville, Pike County, by A. J. Gunderson (pp. 156-186). results secured in each investigation are summarized. An introductory account of the scope and methods of conducting the experiments (pp. 49-57), together with a general summary of the work as a whole, including recommendations for spraying practice in Illinois apple orchards (pp. 187-212) are given by B. S. Pickett.

The experiments as a whole have shown the general effectiveness of applications of standard spray mixtures, including Bordeaux, lime-sulphur, and arsenate of lead in the control of fungi and insects of the apple. Both Bordeaux and lime-sulphur properly used were excellent sprays for the apple. Bordeaux gave greater efficiency as a fungicide but also showed serious tendencies to injure fruit and foilage. Lime-sulphur exercised a fair degree of control of fungi and caused little damage to fruit or foilage. Bordeaux is especially recommended where fungus diseases are known to be serious and also for the cluster bud spray since it seldom injures either fruit or foliage at this stage. In orchards previously cared for the authors advise the use of lime-sulphur for the spray which follows the fall of the petals and for the third summer spray which follows from a week to ten days after the fall of the petals.

Experiments were undertaken to determine whether Bordeaux injury can be lessened or prevented by covering the first spray with a secondary spray of Bordeaux or by maintaining over the Bordeaux a coating of lime throughout the season. Some beneficial effects were observed in certain of the experiments but the work as a whole gave no marked results.

Self-boiled lime-sulphur proved inferior to lime-sulphur made in the usual way as a fungicide although it appeared to exert some stimulating or beneficial effect on the health and vigor of the foliage. Owing to its worthlessness in the control of apple scab it is not recommended as a successful spray for the apple. The addition of copper sulphate to lime-sulphur did not add to its usefulness as a spray. In three of the experiments reported on it resulted in more or less severe injury to the fruit. An application of lime-sulphur made at the strength used for San José scale applied while the trees were dormant was of no value as a preventive of apple scab. Paris green proved less effective than arsenate of lead when used in combination with standard fungicides for the control of chewing insects, particularly the codling moth and the plum curculio, and caused considerable foliage injury.

Arsenate of lead alone possessed practically no fungicidal value and it is recommended that it never be used except in combination with a fungicide.

The addition of arsenate of lead to lime-sulphur appears to increase the fungicidal value of the resulting spray, but its addition to Bordeaux does not increase the fungicidal value of the mixture. In combination with lime-sulphur solution the neutral arsenate of lead produced a spray which was more efficient and safer to use than those arsenates of lead higher in arsenic oxid. The various classes of arsenate of lead when used in combination with Bordeaux showed no important differences in the control of diseases, insects, or injuries to the fruit.

A number of new sprays were tested both as fungicides and as insecticides. Among these it is believed that copper ferrocyanid is worthy of further investigation as a fungicide. The results thus far obtained do not warrant its use except in an experimental way. Copper ferrocyanid failed to show any decided qualities as a poison spray.

With reference to the application of summer sprays in general the work as a whole shows that the first three summer sprays are most useful in improving the grade and quality of the fruit by controlling the majority of the insects and fungi. None of these sprays can be omitted safely. The addition of the fourth and fifth sprays assisted in controlling late-brood codling moth and injury from curculio. A thin but complete coating of the fruit and foliage with Bordeaux-arsenate of lead is more desirable than a heavy coat, except in cases where special protection from curculio is necessary.

Varieties of apples in Ohio, W. J. Green, P. Thayer, and J. B. Keil (Ohio Sta. Bul. 290 (1915), pp. 31-184, figs. 22).—This bulletin contains full horticultural descriptions of the important new or little-known varieties of apples, together with briefer descriptions of the well-known varieties and those of minor importance.

A table showing the disease susceptibility of varieties of apples, prepared by A. D. Selby and others, is given, together with tables showing the adaptation of varieties to sections of Ohio and the quality in different varieties of apples for specific uses.

Water-core of the King David apple, J. B. Keil (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 117, 118, fig. 1).—In this article the author briefly discusses the tendency of certain varieties of apples to form water-core through the accumulation of excess sap in the tissues surrounding the fibro-vascular bundles or core lines. Preliminary tests of a number of varieties including the Winesap, Delicious, Kinnard, and Stayman Winesap indicate that where the water-core is not too severe the excess of sap is again distributed to the surrounding tissues in the ripening process. Recovery seems to be less prevalent in King David than in any other variety tested, the water-core specimens becoming inedible and subject to early decay.

The results of storage tests with King David conducted in 1914 and in 1915 indicate that if this variety is picked with a moderately good color before the water-core develops it may remain either in cold storge or cellar storage for several months without developing water-core. In the tests here reported apples stored about October 12 developed no water-core in storage, whereas with apples stored on October 23 an average of only 31 per cent of the apples was free from water-core.

Peach precooling, E. SMITH (Agr. Gaz. Canada, 3 (1916), No. 2, pp. 121–123, figs. 2).—In some experiments conducted by the Canadian Department of Agriculture precooled peaches were placed in two experimental cars which were iced with crushed ice and 5 per cent of salt in place of block ice without salt, as is the ordinary practice of icing. The results were satisfactory, the temperatures ranging from 30 to 40° F. during an 8-day trip, thus giving better temperatures than are ordinarily secured in block ice cars. There was no evidence of

damage from lower temperatures near the tanks. The cars required a very small amount of ice during transit.

A refrigerator car loaded with precooled fruit showed a rapid cooling down at the beginning of the trip as compared with a slow rate of cooling in a refrigerator car loaded with fruit not precooled.

Pruning the bearing prune tree, V. R. GARDNER (Better Fruit, 10 (1916), No. 9, pp. 9-11, figs. 6).—A discussion of pruning with special reference to the maintenance and proper distribution of fruit spurs in bearing prune trees.

Gooseberries, O. M. Taylor (New York State Sta. Circ. 46 (1915), pp. 5).—Concise directions are given for growing gooseberries, including information relative to the control of insects and diseases and varieties,

Winter protection of the Vinifera grape, F. Garcia and J. W. Rigney (New Mexico Sta. Bul. 100 (1916), pp. 32, figs. 10).—This bulletin describes experiments started in 1906 to determine, among other things, the effect of winter protection upon the vines and yield of five varieties of Vinifera grapes.

Summing up the results for several seasons it was found that the simple banking up of the dirt around the vines protected them during the winter and that the yields were very satisfactory. Unprotected vines were winter injured every time, except once, when there was considerable rainfall during the winter. With reference to resistance to winter temperatures Muscat of Alexandria and New Mexico Mission were most resistant, followed by the Black Cornichon variety. The Emperor and Flame Tokay varieties were slightly less hardy than the Black Cornichon.

Irrigating the vines alone without covering them did not prevent winter injury. Vines that were irrigated either before or right after covering showed no material advantage over those covered and not irrigated, but irrigation either before or after covering did not make the vines any more susceptible to winter injury, and irrigating just before covering makes the plowing of the soil and the banking of the vines easier.

Directions are given for banking up and uncovering the vines. The observations indicate that it is a good plan to uncover the vines from two to four weeks before the pruning takes place, which, at the station, is usually done the first week in April. If the vines are left covered too long the base buds are apt to grow and be injured, either in pruning or uncovering. The two or three weeks difference in time of covering did not show any material influence on the yield. In general it is recommended that the vines be covered from two to three weeks after the first frost.

The hybrid direct bearers in the valley of the Rhone in 1915, A. Des-MOULINS and V. VILLARD (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 37 (1916), *Nos.* 10, pp. 228, 229; 11, pp. 258-260; 12, pp. 274-279; 13, pp. 306-311).—This is the usual progress report (E. S. R., 34, p. 234) relative to the behavior of a large number of hybrid direct bearing grapes, with special reference to their resistance to disease and drought and their adaptation to various soil conditions.

The two groups of varieties of the Hicora pecan and their relation to self-sterility, H. P. Stuckey (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 41-44).—A report of investigations conducted at the Georgia Experiment Station, the results of which are summarized above.

Dahlias and their culture, F. H. Hall (New York State Sta. Circ. 43 (1915), pp. 23, pls. 8).—In this circular the author gives a brief history of dahlias, together with the classification of dahlias as recently adopted by the American Dahlia Society, and descriptive lists of various types of dahlias considered worthy of recommendation for general culture. Concise directions for the culture and care of dahlias are also included.

A street tree system for New York City, Borough of Manhattan, L. D. Cox (N. Y. State Col. Forestry, Syracuse Univ. [Pubs.], 16 (1916), No. 8, pp. 89, pls. 3, figs. 33).—This bulletin comprises a report to the park commissioner for the boroughs of Manhattan and Richmond, and embodies the results of the author's investigation concerning the possibilities for successful tree growth in the Borough of Manhattan.

The subject matter is discussed under the following general headings: The street tree problem in Manhattan, the street tree system, planting types, spacing and arrangement, what trees to plant, how to plant, the cost of planting, organization and budget, the street tree census, and street tree planting in Richmond. A plan showing a proposed system of street planting for the Borough of Manhattan is appended.

The making of a home, E. E. REXFORD (Philadelphia: George W. Jacobs & Co., 1916, pp. 313, pls. 8).—A popular treatise on ornamental gardening.

FORESTRY.

Forest legislation in America prior to March 4, 1789, J. P. KINNEY (New York Cornell Sta. Bul. 370 (1916), pp. 361-405).—This bulletin comprises part of a study presented for the degree of master of forestry at Cornell University.

The bulletin discusses early legislation in the colonies regarding forest fires, the conservation of timber and the prevention of trespass, regulation of the lumber and timber industry, British legislation directed toward the control of forest industries in the colonies, and special developments in forest law during the 50 years preceding the formation of the Union.

A bibliography of consulted literature is appended.

Forest provisions of New York State constitution, C. R. Pettis (Forestry Quart., 14 (1916), No. 1, pp. 50-60).—This paper discusses forest activities in New York State in relation to various forest provisions of the constitution, The text of the conservation amendment proposed by the constitutional convention in 1915 is also given and discussed.

The fire wardens' manual (N. H. Forestry Com. Bul. 5, rev. (1916), pp. 88, figs. 2).—This bulletin contains the laws of New Hampshire relating to forest protection and instruction to forest fire wardens, lookout watchmen, patrolmen, and others connected with the forest fire service.

The Algerian forest code, T. S. Woolsey, Jr. (Forestry Quart., 14 (1916), No. 1, pp. 66-80).—The present forest code of Algeria, which has been in force since 1903, is here given and discussed.

Eighth report of the state forester, 1915, W. O. FILLEY and A. E. Moss (Connecticut State Sta. Rpt. 1915, pt. 3, pp. 193–232, pls. 2).—This report covers the work of 1914 and 1915, and includes the results of a forest survey of the State of Connecticut completed in 1914 and data showing the forest fires in Connecticut during 1914 and 1915. Forest conditions in the different counties of the State are discussed and a detailed table of forest areas by town and county is given, as well as maps showing the percentage of forest land in Connecticut towns and the regions containing the most extensive forest areas in the State. An area of 1,482,700 acres or 46.4 per cent of the area of the State is found to be wooded.

[Report on Indiana Forest Reserve for 1915], E. A. GLADDEN (Ann. Rpt. Ind. Bd. Forestry, 15 (1915), pp. 14-57, figs. 9).—This report consists in the main of a statement of progress made on some 80 forest tracts in the reserve (E. S. R., 33, p. 144).

Twelfth annual report of the state forester [of Massachusetts], F. W. RANE (Ann. Rpt. State Forester Mass., 12 (1915), pp. 130, pls. 8).—This is the usual

annual report relative to the administration and management of the state nurseries and forests in Massachusetts, including also accounts of reforestation work, private cooperative forestry work, and fire protection work. Information is also given relative to the present status of the chestnut blight and white pine blister rust and the work of suppressing the gipsy and browntail moths.

Present conditions of applied forestry in Canada, H. R. Macmillan (Quart. Jour. Forestry, 10 (1916), No. 2, pp. 105-123).—An account of the forest policy in the different Provinces of Canada and its effect on practical forestry.

Silvicultural problems of Canadian forest reserves, B. E. Ferrow (Forestry Quart., 14 (1916), No. 1, pp. 14-23).—A paper on this subject presented to the Commission of Conservation of Canada, Ottawa, 1916. The subject matter embraces the results of an inspection made to formulate propositions for investigatory work as a basis for an eventual technical management of the reserves.

Forest pathology in forest regulation, E. P. MEINECKE (U. S. Dept. Agr. Bul. 275 (1916), pp. 63).—This bulletin comprises a study of the pathology of some white fir stands located on the Crater National Forest in southwestern Oregon. The purpose of the present study is to show by means of one example the problems in forest pathology as related to forest regulation and to furnish some data for the development of laws leading to the regulation of forests, with special reference to the production of sound timber.

Regulation of yield is discussed at some length, consideration being given to working plans, rotation, the cutting cycle, cumulative risk, period of transition, condition of timber stock, total loss, and inferior species. The author's methods of investigation are described in detail and a short review of our present knowledge of the plant pathology of white fir is included. The results of the investigation are discussed under the general headings of decay in relation to wounds, care of virgin forests, forest regulation through timber sales, marking, and pathological rotation and cutting cycles.

Abnormal wood in conifers, W. Somerville (Quart. Jour. Forestry, 10 (1916), No. 2, pp. 132-136, pls. 2).—The author here describes and illustrates a form of wood injury occurring in a number of species of young conifers in the early spring wood of the growth of 1912. The injury is attributed to the excessive heat and drought during the summer of 1911.

The costs and values of forest protection, P. S. Lovejov (Forestry Quart., 14 (1916), No. 1, pp. 24-38).—A discussion of forest protection results on the National Forests and in other countries, with special reference to the status of fire protection as a business proposition. The author concludes that the forest business can fully justify the costs of adequate protection, which will probably approximate 20 cts. per acre per year, of which perhaps 10 cts. will be chargeable to fire protection.

Concerning site, F. Roth (Forestry Quart., 14 (1916), No. 1, pp. 3-13).—A discussion of the importance of site classification as applied to forestry, together with suggestions relative to a basis for such classification.

In an addendum to this paper by H. A. Parker (pp. 12, 13) data are given showing the close relationship of height and volume to site among the pines.

The theory and practice of mixing trees, A. T. GILLANDERS (Quart. Jour. Forestry, 10 (1916), No. 2, pp. 87-104).—This article deals largely with combinations of trees suitable for establishing young forest plantations. Brief reference is also made to ameliorative mixtures and deferred mixtures.

Trees for Kansas, C. A. Scott (Kansas Sta. Circ. 55 (1916), pp. 19, figs. 9).— Lists are given of trees and native shrubs suited to different sections and soils in Kansas, together with general directions for the planting and care of trees. Data are also given showing the results secured from trees sent out by the state nursery during four seasons.

The junipers and their commercial importance, W. Dallimore (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 1 (1916), pp. 16-23).—Descriptive notes dealing with cedar woods in a previous article (E. S. R., 29, p. 842) are here extended, and descriptions are given of other species of juniper not so well known commercially as cedar.

Rattan supply of the Philippines, J. R. Arnold (U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 95 (1915), pp. 40).—A statistical report on the supply of Philippine rattan and its suitability as to quality, cost of exploitation, etc., for placing in quantities on the export market.

Wood-using industries of West Virginia, compiled by J. C. Nellis and J. T. Harris (W. Va. Dept. Agr. Bul. 10 (1915), pp. 144).—This embraces the results of a study of the wood-using industries of West Virginia, conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the State of West Virginia. Information is given relative to the principal woods of the State; the kinds and amounts of woods used in the industries, including those grown in the State and out of the State; and the uses of the various woods.

By-products of the lumber industry, H. K. Benson (U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 110 (1916), pp. 68, pl. 1, figs. 10).— This bulletin embraces the results of a survey relative to the utilization of the by-products of the lumber industry in the United States. Consideration is given to the utilization of wood in the wood-distillation industries, pulp manufacture, and tannin-extract manufacture. The other industries discussed are the manufacture of ethyl alcohol, producer gas, oxalic acid, plastics, and needle oils. A general account is given of methods and processes employed, together with data showing the extent of the industries.

An efficient system for computing timber estimates, C. E. Dunston and C. R. Garvey (Forestry Quart., 14 (1916), No. 1, pp. 1, 2, pl. 1).—A simple device for holding timber estimate sheets and volume tables when computing estimates on adding machines is here illustrated and described.

DISEASES OF PLANTS.

Work connected with insect and fungus pests and their control, W. Robson (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Montserrat, 1914–15, pp. 18–20).— The staining of cotton is thought to be due to some organism not yet identified which is given entrance by the stainer insect when it pierces the boll in order to extract the juices from the seed. A number of other injurious insects are reported upon.

Experiments with Bordeaux mixture for control of leaf rust of peanuts (*Uredo* sp.) resulted in an increase of yield. This outcome was in contrast with that of two previous tests, which were, however, made later in the season.

Puccinia maydis, not previously recorded here, was noted as general in one field. A field of young maize plants to leeward of an old infected field showed pustules of the fungus three weeks after the time of its planting.

Tephrosia candida was attacked by Neocosmospora vasinfecta.

Flower heads of implies (sorghum) were reported to be attacked by *Sphacelotheca sorghi*. The formalin treatment (1 lb. to 30 gal. water) is said to be convenient and safely preventive.

Damping off of onion seedlings in the seed bed, caused by a fungus or fungi, is said to be prevented by thoroughly heating the soil for some time or by use

of formalin (1 part to 50 of water), or by a layer of sand on the surface of the seed bed.

A lace bark tree (*Lagetta lintearia*) was killed by *Lasiodiplodia theobroma*, said to be a common cause of injury to cacao and other trees.

The ornamental plant *Plumbago rosea* was attacked and injured by nematodes, which may also be the cause of swellings on Echiums.

Mycological and pathological notes, M. Turconi and L. Maffei (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 12 (1915), pp. 329-336, pl. 1).—The authors describe as having been found on leaves of ash received from Mexico, Cercospora lumbricoides, n. sp.; on a branch of Castilloa elastica from the same source, Nectria castilloa n. sp.; and on twigs of mulberry from Bulgaria, Steganosporium kosarofii n. sp.

Review of plant diseases, G. Scalia (Bol. Min. Agr., Indus. e Com. [Romc], Ser. B, 14 (1915), I, No. 2, pp. 52-63).—This is a condensed review of cryptogamic diseases, animal parasites, etc., of plants as studied in the laboratory for vegetable pathology in the school of enology at Catania, during 1910–1913.

Annual report of the government botanist for 1914–15, W. SMALL (Ann. Rpt. Dept. Agr. Uganda, 1915, pp. 57–70).—Coffee leaf disease (Hemileia vastatrix) is reported as having decreased since 1913, apparently of its own accord. Spraying is recommended as a preventive, especially in case of young estates,

Coffee dieback, in so far as it has not been due to attack by Hemileia, is regarded as the direct effect of a form of overbearing by the branches intermediate between the basal and apical regions. The remedy consists in cutting away all the part above the early branches and reproducing the top by means of a new sucker from the stump, also in relieving the intermediate branches of their heavy first crop. Good cultivation is a necessity. Of the fungi noted in this connection none appears to be constantly present.

Brown root disease of coffee, due to *Hymcnochate noxia*, has usually been traced to a dead stump or log, frequently of unknown species. The mycelium, however, can not make its way through the soil, so that only the older trees are attacked.

Sooty mold of coffee, due to *Capnodium brasiliense*, is checked by killing the insects which it follows with a spray of whale oil soap solution. An anomaly in the flowering of Uganda coffee was noted in which no pollen was shed, owing to nondehiscence of the anthers.

Cacao was very little diseased. A dieback was attributed to a fungus showing, apparently, the Diplodia spores of *Thyridaria tarda*. These are thought to cause also a dieback of Hevea, and in part at least a pod disease of cacao which in other cases was associated with *Colletotrichum incarnatum* and later with *Phytophthora faberi*. A root disease of cacao is described which is thought to have had its origin in native plants previously cultivated.

Heve also showed few diseases, Hymenochate noxia being the only root disease as yet certainly identified. A dieback was associated with T. tarda, Phyllosticta ramicola, and Phoma hevew, but not with Glwosporium alborubrum, previously noted in this connection. Hevea canker has not been reported.

Ceara rubber (Manihot glaziovii) is often attacked and ruined by Loranthus entebbensis.

Cotton is free from fungus disease except in case of *Ramularia areola*, which is confined chiefly to young plants, the leaves of which are attacked, usually not very severely. Wheat in some sections is attacked by *Puccinia graminis*. Maize is attacked by head smut (*Sorosporium reilianum*), which is not known to have been reported previously in Uganda.

Mention is made of several other fungi known to attack various wild or cultivated plants in Uganda.

An anatomical study of Gymnosporangium galls, A. Stewart (Amer. Jour. Bot., 2 (1915), No. 8, pp. 402-417, pls. 2, fig. 1).—The author states that the large galls which G. juniperi-virginiana and G. globosum cause on the younger branches of Juniperus virginiana arise from the axils of the leaves, being evidently transformed axillary buds. They are said to have two distinct fibrovascular systems, one of which is a leaf-trace system and the other a stem which, in case of the older galls, gradually breaks up and radiates outwardly still deeper into the gall tissue. Leaf tissue is also involved in the formation of a gall, remains thereof being found usually adhering to the older galls.

Normal stems sometimes appear to have grown out from the surface of the older galls. Accessory stem structures occur, probably originating in a branching of the main stem in the gall. Broad, ray-like masses of parenchyma, surrounded by tracheids, are of somewhat common occurrence. Irregularly twisted masses of fibrovascular tissue resembling like structures in traumatic wood also occur. Cells apparently transitional between parenchyma and tracheids are not uncommon. The irregularly running bundles in the gall are composed largely of scalariform tracheids.

A bibliography is given.

Calcium hypochlorite as a seed sterilizer, J. K. Wilson (Amer. Jour. Bot., 2 (1915), No. 8, pp. 420-427).—The author gives a summarized compilation of the methods employed by the several investigators named in this connection, and describes his own experiments for sterilizing seeds with calcium hypochlorite.

The considerable number of tests made and the results obtained as shown are held to demonstrate the efficacy of the method used, employing the bleaching powder as an aid in securing sterile plantlets from seed. Ease of application and freedom of the seed from injury except after long exposure are further advantages claimed for the method. The effect of the solution is thought to be due to the hypocholorous acid, which acts as a toxic agent.

Some notes on Bordeaux and Burgundy mixtures, S. F. Ashby (Jour. Jamaica Agr. Soc., 19 (1915), No. 9, pp. 342-345).—Discussing the composition and merits of some proprietary and other spraying preparations, the author concludes that the ready-made powders intended to replace homemade Bordeaux and Burgundy mixtures are prepared on the wrong principle, being merely mechanical mixtures of the ingredients and not the finished product of their mutual action, so that the great advantage of a finely suspended solid, which can be secured only by mixing weak solutions, is lost, and a coarse, rapidly settling mixture results. The homemade mixtures are deemed less expensive and more satisfactory as to results, but somewhat more troublesome to prepare. Formulas and directions for their use are given, and the relative costs are discussed, with the particular adaptations of each preparation.

Tests with Perocid, F. STRANAK (Deut. Landw. Presse, 42 (1915), Nos. 62, pp. 537, 538; 63, pp. 544-546, figs. 7).—This is an account of tests with a proprietary preparation containing certain radio-active substances. For this value is claimed as a fungleide, chiefly in connection with cereals, and also as an energizer of the growing plantlets.

Experiments on the control of cereal diseases by steeping the seed grain, E. Riehm (Illus. Landw. Ztg., 35 (1915), No. 24, pp. 161, 162).—Good results as regards smut control are claimed to have been obtained by soaking the seed grain from 10 to 60 minutes in 0.1 to 0.2 per cent of mercury chlorophenol, or in 0.1 per cent of corrosive sublimate, or for 15 minutes in 0.1 per cent of formaldehyde (which was less injurious to germinability), but less satisfactory results followed the use of 0.1 per cent of chinosol for 10 to 20 minutes, or of 0.2 per cent of chinosol for 5 to 15 minutes.

Leaf stripe (*Helminthosporium gramineum*) appears not to have been lessened by steeping the grain in formaldehyde of 0.1 per cent strength for from 10 to 30 minutes, but copper sulphate of 0.5 per cent strength for the same period reduced the disease considerably, and 1 per cent reduced attack to about 0.5 per cent of the grain sown. Mercury chlorophenol and chinosol also appear to be practical remedies for leaf stripe.

Tests on the control of Fusarium in relation to the preservation of germinability are considered to show that chinosol is not to be recommended unreservedly in this connection. Uspulum, a trade preparation of mercury chlorophenol, is said to have about equal value with corrosive sublimate, while formaldehyde has somewhat less.

Smut control, O. Appel (Mitt. Deut. Landw. Gesell., 30 (1915), No. 37, pp. 551, 552).—This is a discussion of some methods for the control of grain smuts which are claimed to be sufficiently safe, suitable, and inexpensive to warrant their employment in the present situation in Germany. These include washing the seed grain by hand, treating with from 0.1 to 0.2 per cent of formaldehyde, and steeping in water at 45° C. (113° F.) for two hours or at 40° for from six to eight hours, or a combined treatment by steeping in water at from 25 to 30° for four hours (or one hour and covering the grain from six to eight hours) and then for from five to ten minutes in water at from 50 to 52°.

[Grain rusts], E. Riehm (Deut. Landw. Presse, 42 (1915), No. 49, pp. 433, 434, pl. 1, fig. 1).—This is a descriptive discussion of black rust (Puccinia graminis) on wheat, rye, barley, and oats; yellow rust (P. glumarum) on wheat, rye, and barley; brown rust (P. triticina) on wheat; brown rust (P. dispersa) on rye; crown rust (P. coronifera) on oats; and dwarf rust (P. simplex) on barley.

[Injurious influences affecting winter rye], K. Störmer (Deut. Landw. Presse, 42 (1915), Nos. 65, pp. 559-561; 66, pp. 572, 573, fig. 1).—This is a discussion of weather, soil, and plant and animal parasites as affecting rye production in 1914–15 in Pomerania, with more particular reference to Fusarium as related to foot rot and to remedies therefor. A proprietary preparation of corrosive sublimate is recommended as preferable to copper sulphate or formaldehyde in this region.

Climatic conditions as related to Cercospora beticola, Venus W. Pool and M. B. McKay (U. S. Dept. Ayr., Jour. Ayr. Research, 6 (1916), No. 1, pp. 21-60, pls. 2, fiys. 10).—The results are given of a study carried on at Rocky Ford, Colo., from 1911 to 1913, and near Madison, Wis., during 1914, to determine the climatic conditions of both winter and summer as bearing on the vitality and development of C. beticola. Notwithstanding the differences in temperature and soil moisture conditions, similar results were obtained from the overwintering experiments at both places.

When exposed to outdoor conditions, the conidia of the fungus die in sugar beet top material in from one to four months, but when kept dry, they may remain alive as much as eight months. The sclerotia-like bodies which are embedded in the tissues of the host are more resistant than the conidia and live through the winter when only slightly protected, becoming a source of infection for the succeeding crop.

Tests of artificial cultures showed that exposure to constant temperatures of from 95 to 97° F. was fatal to the growth of the fungus, but that when exposed for three days to either of these temperatures and then changed to 87°, growth followed, as was also the case when cultures were held at either of these temperatures for eight hours and then at 68° for 16 hours. A temperature of 105° was found fatal in all combinations tested.

Temperature and relative humidity were found to influence production of conidia and infection in much the same way. A temperature of from 80 to 90°, with a night minimum preferably not below 60°, was most favorable to conidial production, which was checked by a temperature of 100° or higher and retarded by a range from below 50 to 80°. A maximum humidity ranging above 60 for not less than 15 to 18 hours each day induced a good growth of the fungus. Because of the higher humidity on the lower than on the upper surface of the leaf, the conidia are generally more abundant on the lower surface of the spots, and because of the action of rain and wind they disappear more rapidly from the upper surface.

Control of club root of crucifers, F. Burkhard (Möller's Deut. Gärt. Ztg., 30 (1915), No. 34, pp. 274, 275, fig. 1).—Control measures recommended for Plasmodiophora brassicæ, causing club root of crucifers, include rotation, the application of 500 gm. of freshly slaked lime per square meter in the fall, followed in the spring by 50 gm. of a potassium salt with well rotted compost, careful selection of stock for planting, and removal of any unthrifty plants.

Flax disease investigations (North Dakota Sta. Rpt. 1915, pt. 1, p. 16).—The investigations in flax diseases, which have been in progress for some time, are briefly described. Special centgener plantings have been made to increase resistance of flax to rust and wilt.

The results for the year covered by this report are said to indicate that resistance can be developed to an extent that will practically control these diseases. Trials were made of seeds sent in by farmers to be tested for resistance, the results of which seem to indicate that resistance power, when once acquired, will endure for a considerable period, even though the crop is grown on ground free from the diseases. Crops grown from seed which had been wet, moldy, or frozen showed diminished powers of resistance.

A Rhizoctonia disease of licorice, W. HIMMELBAUR. (Ztschr. Landw. Versuchsw. Österr., 17 (1914), No. 8-9, pp. 671-683, figs. 9).—Giving the results of microscopic and microchemical studies on a Rhizoctonia disease said to decrease materially the returns from Glycyrrhiza, the author describes the development of the fungus and of the alterations caused thereby. It is stated that the diseased portion soon takes on somewhat the character of a foreign body, having been separated more or less completely by a cork layer from the healthy portions.

Investigations of potato diseases (North Dakota Sta. Rpt. 1915, pt. 1, pp. 17, 18).—It is reported that the Fusarium wilt, Fusarium rot, brown stem rot, Rhizoctonia, and leaf roll of potatoes are of economic importance in the potato districts of North Dakota. These diseases appear to be more active in the lighter soil areas, while early blight is reported as occurring extensively in the region of heavier soils.

The frequent occurrence of Rhizoctonia on potato vines has led to a study of that organism. In samples of soil collected from 24 plats that had been devoted to crop rotation for 24 years, 18 lots showed the presence of *Corticium vagum*. Many of these plats had not been cropped to potatoes for many years. As a result of the investigation it is considered probable that Rhizoctonia occurs on the roots and débris of a large variety of plants, and that the present method of treating seed potatoes to avoid this disease is correspondingly futile.

Potato diseases, O. Schlumberger (Deut. Landw. Presse, 42 (1915), No. 41, pp. 369, 370, pl. 1).—This includes a description of Phytophthora tuber rot, bacterial wet rot, Fusarium or dry tuber rot, verticilliose or wilting disease, bacterial ring rot, hollow tubers, various spotting diseases, Oospora scab, Spongospora powdery scab, canker (Chrysophlyctis endobiotica), and Rhizoctonia disease. Some preventive and remedial measures are also discussed.

Filosity in young potato plants, P. Passy (Jour. Soc. Nat. Hort. France, 4, scr., 15 (1914), July-Dec., pp. 500, 501).—Of two potato tubers which had been subjected to the same conditions, one was shown to have produced normal sprouts, while the other exhibited a clearly marked case of filosity. The facts are supposed to refute the views of Parisot (E. S. R., 23, p. 148) that this abnormality in growth is due to an accumulation of carbon dioxid during storage.

Downy mildew (Sclerospora macrospora) on rice, L. Gabotto (*Gior. Risicolt.*, 5 (1915), No. 18, pp. 292–294, fig. 1).—A disease of rice is described as due to S. macrospora. The head, if it emerges, is distorted and empty of grain, owing to atrophy or transformation of the essential floral organs.

A stem disease of sugar cane in Barbados, W. Nowell (Agr. News [Barbados], 15 (1916), No. 357, p. 14).—The author has examined a sugar cane disease appearing in Barbados, said to be similar to or identical with that occurring in India and described by Butler and Hafiz (E. S. R., 30, p. 650) as due to Cephalosporium sacchari.

The disease appeared to be partly or entirely confined to canes whose water supply had been interfered with as a result of wrenching by high winds or of the development of *Marasmius saechari* in the cane base. Some of the symptoms resembled those of red rot. *Melanconium saechari* usually appeared as a secondary infection.

C. sacchari is thought to be widely distributed in the West Indies, and it may be a factor in what appears to be a somewhat serious disease.

Sweet potato diseases, L. L. Harter (U. S. Dept. Agr., Farmers' Bul. 714 (1916), pp. 26, figs. 21).—This is a compilation of popular information regarding sweet potato diseases, which, it is said, may be divided into three general classes, those attacking the roots and stems, stem rot, black rot, foot rot, scurf, and root rot; those of the leaf, leaf blight, white rust, and leaf spot; and those developed in storage, soft rot, black rot, dry rot, Java black rot, and charcoal rot. The different diseases are described and suggestions given for their control.

Apple rust, N. J. Giddings and A. Berg (West Virginia Sta. Bul. 154 (1915), pp. 4-73, figs. 41).—This is a detailed account of investigations of apple rust and its control, a preliminary account of which has been noted (E. S. R., 33, p. 348). In the present bulletin, a technical account is given of the organism, Gymnosporangium juniperi-virginianæ, its distribution, conditions for infecting the host plants, and its physiological effect on both apple and cedar, after which spraying and other methods of control are described.

The authors report that apple leaves are susceptible only when young, and that rust infection is not likely to take place after the first week in June in the latitude of the station. Severe rust infections cause a deforming of the fruit and a reduction in size, with a considerable loss of vigor in the tree.

It is said that the disease may be controlled by the use of Bordeaux mixture, lime sulphur, or atomic sulphur, lime sulphur being the most efficient, but the use of fungicides is deemed impracticable for commercial orchardists. The destruction of cedar trees is considered a more effective method of control, and this has been carried out on a small scale, 1,113 acres being cleared of cedar trees at a cost less than 48 cents per acre.

A disease of apricot in Valais, H. FAES (Terre Vaud., 6 (1914), No. 25, pp. 282, 283).—Referring to a report made to the Department of Valais, Switzerland, on a disease of apricot observed to be particularly severe at Saxon in 1914, the author states that the trouble, which is described as due to Monilia fructigena (M. laxa), causes much loss following damp weather and rains.

Preventive treatments, including copper sprays and polysulphids, have not proved to be effective. Suggestions are given regarding the employment of phosphorus and potassium fertilizers and measures for securing earlier ripening of the wood.

A disease of apricot in the Rhone Valley, J. CHIFFLOT and MASSONNAT (Rev. Hort. [Paris], 87 (1915), No. 27, pp. 540, 541).—In portions of the Rhone Valley apricot trees are said to be affected with a disease characterized by the drying of the flowers, leaves, and young branches, followed by gummosis, separation of the bark from the wood, and discoloration of the latter. The trouble appears to be caused by the same fungus as that reported above by Faes as occurring in Switzerland.

Spring conditions will not permit the use of strong sprays, but removal of all affected portions is recommended. In winter, the use of copper sprays at 1.2 per cent strength is advised, with the addition of soap and gelatin to secure better spreading and adhesion.

Summer outbreaks of downy mildew, H. Faes (Terre Vaud., 6 (1914), No. 32, pp. 338-341).—Recent tests have confirmed the view that mildew attack on grape leaves occurs by way of the lower surface only, and that spraying from below is sufficient if the fungicide is applied thoroughly and in proper strength, preferably with an admixture of materials suited to increase its spreading and sticking qualities. The attack is said to occur mainly when the leaves are young, but it may occur later.

Spotting of citrus fruits, H. S. FAWCETT (Mo. Bul. Com. Hort. Cal., 4 (1915), No. 9, pp. 434, 435).—It is stated that for a number of years past, especially during moist, cool weather, lemons and sometimes oranges have been observed to develop, after coming to the packing house, green spots which may later become brownish or reddish and somewhat sunken, and which do not increase in size after their formation.

It has been shown that typical green spots can be developed by so pressing and rolling lemon fruits against boards as to cause injuries, also that oil from one lemon pressed out on the injured surface of another produced the typical sinking of the tissue between the oil cells. Green spots were produced by presssure on the surface of the rind sufficient to liberate the oil but not sufficient to cause a visible break in the rind. It has also been noticed that picking green fruit while wet favored the formation of the spots. The oil on fruit kept in moist air produced a greater effect than on fruit kept dry, which is thought to be due to its slower volatilization under these circumstances.

The picking of the fruit only under dry conditions is recommended.

Work connected with insect and fungus pests and their control (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica, 1914–15, pp. 11–17, fig. 1).— This reproduces a preliminary report by W. Nowell on his investigation of the black root disease of lime trees in Dominica caused by Rosellinia bunodes, said to be the only disease of lime trees of really serious importance in the island at the time. The disease is known only on estates with fairly recent forest clearings. It is thought to be distinct from a closely similar disease on cacao. Soil and situation favorable to the rapid development of the lime trees seem also to favor the disease. The greater seriousness of the disease during the years reported upon is ascribed largely to a period of extremely wet weather, but still more to the cumulative character of the disease and the increased number of contacts among the growing and interlacing roots. On reaching the light, the fungus produces spores, which can cause infection some distance from the point of origin.

It appears that thorough ventilation of the collar and of the main roots near their points of attachment, in addition to rendering early detection easy, may considerably delay, if not stop, the progress of the disease. The use of carbon bisulphid is to be tested in connection with this disease. The first precaution, the destruction of the trees by fire, is said to be rendered easy by the inflammable nature of the wood.

As no case of the disease on sour orange has been noted, it is thought that this apparent immunity, if confirmed, may prove to be of great importance. A system of isolation and drainage is shown to have been effective in the one instance in which it was given a thorough trial, as the trees looked well and dying in patches was entirely prevented.

The pink disease of lime branches due to *Corticium lilacino-fuscum* is said to exist on some estates. While it is not yet sufficiently abundant to possess much economic importance, destruction of diseased branches is advised.

Diseases of tulip and hyacinth, J. C. T. UPHOF (Möller's Deut. Gürt. Ztg., 30 (1915), Nos. 37, pp. 295, 296; 38, pp. 306, 307).—The author suggests the trial in connection with the ring disease of hyacinth and tulip of the plan which J. Ritzema Bos is said to have found successful with onions. This consists essentially in the treatment of the soil about the end of March, before planting in the middle of April, with lime and ammonium sulphate, ammonia being set free and giving practical disinfection of the soil.

A disease of tulip due to *Sclerotium tuliparum*, which also frequently attacks *Iris hispanica*, occasionally hyacinth, gladiolus, and *Fritillaria imperialis*, and rarely narcissus, is thought to be controllable by the three-year rotation, tulips, potatoes, and hyacinths. The disease of tulip caused by *Botrytis parasitica* is most satisfactorily dealt with by removal and destruction of affected plants.

Variation and blight resistance among walnuts, L. D. BATCHELOR (Mo. Bul. Com. Hort. Cal., 4 (1915), No. 9, pp. 428-430).—Giving the results of observations on productivity, blight resistance, and season, the author states that this disease is the greatest limiting factor for walnut production in the principal walnut growing countries. It is considered that a tree which has only 10 per cent of blighted nuts in an orchard which averages from 70 to 80 per cent may be really more resistant than one apparently free from disease among others which are only from 15 to 20 per cent blighted. Examples given show a wide range of susceptibility to attack in different varieties named.

Contributions on the life processes of oak mildew, J. Roth (*Naturw. Ztschr. Forst u. Landw.*, 13 (1915), No. 6-7, pp. 260-270).—The author presents, as supplementary to five work of Neger (E. S. R., 33, p. 745), his own observations and experiments on oak mildew.

The fact that this disease flourishes best in situations exposed to sunshine is thought to be attributable to the influence of the sun on the host rather than on the parasite, which prefers the tender, later maturing growth made by the shoots in open situations. The relations of shading to parasitic growth in case of other plants are also discussed.

The publications of the Pennsylvania Chestnut Tree Blight Commission (Harrisburg: State, 1915, pp. 641, pls. 180, figs. 7).—This is a collection of the papers issued by the Pennsylvania Chestnut Tree Blight Commission, most of which have been previously noted.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

The prairie dog situation in Colorado, W. L. Burnett (Off. State Ent. Colo. Circ. 17 (1915), pp. 15, figs. 2).—This circular, which is intended to replace Circular 8, previously noted (E. S. R., 30, p. 249), deals with the occurrence of the plains prairie dog (Cynomys ludovicianus), the white-tailed prairie dog (C. leucurus), and the Gunnison prairie dog (C. gunnisoni) in various counties

of Colorado. A brief description is then given of their habits and economic status and methods of combating.

The prairie dog situation, R. K. NABOURS (Kansas Sta. Circ. 54 (1915), pp. 4).—This abridgment of Circular 4, previously noted (E. S. R., 22, p. 457), treats of the methods of combating prairie dogs.

Meadow mice, W. L. Burnett (Off. State Ent. Colo. Circ. 18 (1916), pp. 11, figs. 2).—A brief description is given of five species and subspecies of Microtus found in Colorado. The food habits of the different species are so similar that they are treated as a whole, and brief consideration is given to their natural enemies, damage in the United States, possibility of an outbreak in Colorado, how to save girdled trees, breeding, and methods of combating.

Effect of 186-515 generations of Danysz bacillus in a ten per cent decoction of egg albumin on the gray rat (Mus decumanus), S. S. Merezhkovskii (Trudy Selsk. Khoz. Bakt. Lab., 4 (1913), pp. 138-149).—A mortality of 84 per cent was caused among gray rats fed upon the Danysz bacillus (generations 186-515), obtained by their uninterrupted culture in a 10 per cent decoction of egg albumin.

Duration of the virulence of agar cultures of the Danysz bacillus, S. S. Merezhkovskii (*Trudy Sclsk. Khoz. Bakt. Lab., 4* (1913), pp. 181-185).—The investigations here reported show that the virulence of agar cultures of the Danysz bacillus may be preserved for at least 1.5 years when kept under favorable conditions.

Experiments made in 1912 in the Government of Bessarabia with the Siberian marmot, S. S. Merezhkovskii (*Trudy Selsk. Khoz. Bakt. Lab.*, 4 (1913), pp. 207-236, figs. 4).—A report of experimental work with the Danysz bacillus in which unsatisfactory results were obtained due to the high natural mortality which occurred among the rodents.

On Giardia microti sp. nov., from the meadow mouse, C. A. Kofold and ELIZABETH B. CHRISTIANSEN (Univ. Cal. Pubs., Zool., 16 (1915), No. 2, pp. 23-29, fig. 1).—This species causes inflation of the intestines of the meadow mouse, the walls of the intestines becoming thin and flaccid and assuming a yellowish-orange color in the infected region.

Propagation of wild birds, H. K. Job (Garden City, N. Y.: Doubleday, Page & Co., 1915, pp. XII+276, pls. 65).—A manual of applied ornithology treating of practical methods of propagation of quails, grouse, wild turkey, pheasants, partridges, pigeons and doves, and waterfowl in America, and of attracting and increasing wild birds in general, including song birds.

A new interpretation of the relationships of temperature and humidity to insect development, W. D. Pierce (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 25, pp. 1183-1191, figs. 2).—The studies here presented are based principally upon records of thousands of individual boll weevils (Anthonomus grandis and A. grandis thurberiæ) made by agents of the Bureau of Entomology of this Department in the Southwest extending over a long period of years.

Following a brief introduction and discussion of experimental methods, the subject is dealt with under the headings of zones of climatic relations, effective temperature, zone of inactivity, nomenclature of climatic effects on life, and practical applications. The author describes his method of computing effective temperatures and with a chart shows his method of determining the zone of effective temperatures at a humidity of 56 per cent. A chart and data are also given which show the relations of temperature and humidity to cotton boll weevil activity.

Attention is called to the fact that only in recent years has it been generally accepted that each species of insect, etc., may have a different zero of effective

temperature. It is pointed out that there is an absolute minimum fatal temperature below which, even for the shortest time, life is impossible and that there is also a corresponding absolute maximum fatal temperature; and that absolute dryness is more or less prohibitive of life, as is absolute humidity, i. e., saturation.

In working out the relation of temperature and humidity the diagrammatic figure sought has four definite absolute boundaries—the maximum and minimum temperatures and humidities. "Within the limits which we have thus defined there exist conditions under which all the activities of the species reach their maximum efficiency. It has been conceived by most writers that this maximum efficiency was reached at a definite point known as the optimum. It seems more likely that it will prove to be a zone of humidities and temperatures of more or less restricted area. A careful study of the records of any species, charting for the time required for each activity and the temperature and then similarly for humidity, will disclose temperature and humidity points of maximum efficiency. With the boll weevil these points lie approximately near 83° F. and 65 per cent of relative humidity."

Hydrocyanic acid gas.—Its practical use as a routine fumigant, R. H. Creel, F. M. Fager, and W. D. Wrightson (*Pub. Health Rpts.* [*U. S.*], 30 (1915), No. 49, pp. 3537-3550, fig. 1).—The authors here present the results of 19 practical experiments with hydrocyanic acid gas.

The results of several experiments with decreasing amounts of chemicals indicate that the use of 5 oz. of potassium cyanid to 1,000 cu. ft. of space is as effective as twice that amount. "It was clearly demonstrated that the quickest and best results were obtained by the use of powdered potassium cyanid, the chemical action being much facilitated and more rapidly completed. . . . Attempts to destroy bacteria with this fumigant were unsuccessful.

"It was noticed that where the rodents were allowed to run at liberty within the room during fumigation, and in the cases of the more active ones in cages, the effects of the gas were earlier apparent and more marked, and the rodents succumbed more quickly. Any physical efforts of the rodents seemed to hasten the effects of the gas, presumably by increased respiratory action. The cyanid gas apparently diffuses very rapidly, rising first to the top of a closed space, thence following along the walls to the floor, and finally reaching the center of the space."

Cyanid gas was found to be much more penetrating than sulphur dioxid, and thus it is to be preferred for fumigating ships loaded with cargoes. From the experiments it would seem that one-half hour is sufficient exposure when cyanid gas is used as a fumigant, and that the increasing of this period to one hour ought to suffice, even when unusually large spaces are fumigated. One of the experiments indicates that holds of ships will not retain cyanid fumes so as to be dangerous to life 30 minutes after the hatchways are removed.

Fifteenth report of the state entomologist of Connecticut for the year 1915, W. E. Bertton (Connecticut State Sta. Rpt. 1915, pt. 2, pp. VII+81-192, pls. 17, flys. 6).—The first part of this report is taken up by a statement relating to the finances and routine work, including the inspection of nurseries, of imported nursery stock, of apiaries, etc.

Reports of Gipsy Moth Suppression Work in 1915 (pp. 99–111) and of Brown-Tail Moth Work, Season of 1914–15 (pp. 111–114), by W. E. Britton and I. W. Davis, next presented, are followed by a report of Experiments in Controlling the Cabbage Maggot in 1915, by W. E. Britton and Q. S. Lowry (pp. 114–118) in continuation of investigations of 1914, previously noted (E. S. R., 33, p. 58). The season was particularly favorable for control experiments, as the maggots were very abundant and caused more damage than usual. The best results

appear to have been obtained from the use of tar paper disks, the infestation of the plants thus protected being 4.4 per cent as compared with an infestation of 6 per cent on plants treated with crude carbolic acid emulsion.

A general account of A Destructive European Pine Sawfly in Connecticut (Diprion [Lophyrus] simile) is next presented by the author (pp. 118-125). This sawfly, an account of which has been previously noted (E. S. R., 34, p. 363), was first discovered in a nursery at New Haven in August, 1914. Since the publication of the article mentioned, it has also been found at Derby, Hartford, New Canaan, and Greenwich.

An account is next given of the Larch Sawfly (Lygavonematus [Nematus] erichsonii) (pp. 125–134), which, although it has undoubtedly occurred in Connecticut for many years, was not observed until 1915 when specimens were received from East Canaan. Accounts by Hewitt relating to this pest have been previously noted (E. S. R., 28, p. 658).

Experiments in Controlling the White Pine Weevil in 1915 (pp. 134–136) and Fumigating a Grapery with Hydrocyanic Acid Gas to Kill Mealy Bugs (pp. 136, 137) are reported upon by B. H. Walden. Brief accounts of The Juniper Webworm (Dichomeris marginellus) (pp. 137–139) and Three Species of Scale Insects New to Connecticut, namely Leucaspis japonica, Lepidosaphes newsteadi, and Diaspis echinocacti (pp. 139, 140), and a discussion of Mosquito Conditions in Connecticut in 1915 (pp. 141–144) follow. The Report on a Mosquito Survey at the Mouth of the Connecticut River, by P. L. Buttrick (pp. 144–172) has been previously noted (E. S. R., 34, p. 856). A discussion of the Changes in the Vegetation of Salt Marshes Resulting from Ditching, by W. E. Britton, B. H. Walden, and P. L. Buttrick (pp. 172–179), and an account of White Grub Injury in 1915 (pp. 179–181) are next given.

The report concludes with a brief discussion of the entomological features of 1915 (pp. 181-183) and of miscellaneous insect notes (pp. 183-191), relating to the banded fleabeetle (Systena tuniata) which was ablidant and caused injury to beans, tomato, eggplant, and sunflower at North Haven by feeding upon the leaves; unusual galls upon wild rose; the lime tree spanworm (Erannis tiliaria) found feeding upon the birch at New Haven; a parasite of the San José scale, Prospattella perniciosi, a large number of which were reared during the year; the buffalo tree hopper which injured apple twigs at Wethersfield; a leaf roller on privet (Archips rosana); the false apple red bug (Lygidea mendax), which was the source of considerable injury in the southwestern corner of the State; a sawfly on imported manetti rose stock (Emphytus cinctus); the linden borer (Saperda vestita), said to have caused considerable injury to linden trees; two psyllids new to Connecticut, namely, Psylla buxi and Spanioneura fonscolombii; the strawberry rootworm (Typophorus canellus) at New Haven; a woolly aphis (Pemphigus acerifolii) on silver maple at Derby; white ants (Leucotermes [Termes] flavipes) in a house at Ridgefield; the chrysanthemum leaf miner (Phytomyza chrysanthemi); a new leaf weevil in Connecticut (Polydrusus impressifrons); a tortricid (Tortrix albicomana) on oak; the iris borer (Macronoctua onusta); mites (Rhizoglyphus hyacinthi) injuring Bermuda lilies; a new enemy of peach trees (Diplotaxis atlantis); and aphids (Aphis rumicis, Macrosiphum solanifolii, and Myzus persica) on seed beets.

[Economic entomology] (Ztschr. Angew. Ent., 1 (1914), No. 2, pp. 244–320, figs. 24).—The papers here presented include the following: The Occurrence of the Pink Bollworm (Gelechia gossypiella) in Egypt, by A. Andres (pp. 244–247); The Grapevine Moths or Traubenwicklers (Polychrosis botrana and Cochylis ambiguella) and Their Natural Enemies in South Tyrol, by C. Catoni (pp. 248–259); Injurious and Beneficial Insects in Dry and Manufactured Tobacco,

by K. Escherich (pp. 260–265); The Status of Economic Entomology in India, by H. Morstatt (pp. 266–271); The Relation of *Stomoxys calcitrans* to Infantile Paralysis, by K. H. C. Jordan (pp. 272–276); The Mycological Investigations of Fungus Diseases of Insects and Economic Entomology, by G. Lakon (pp. 277–282); and The History of Nematus Injury in the Royal Saxony State Forest Reserve of Naunhof near Leipsic, by P. Jachn (pp. 283–320).

Report of the economic biologist, G. E. Bodkin (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1913-14, App. 3, pp. 11).—A brief statement of the work of the year, including revised lists of insects injurious to sugar cane with their parasites and of the insect pests of the coconut palm in British Guiana.

Report of the imperial entomologist, T. B. FLETCHER (Rpt. Agr. Research Inst. and Col. Pusa, 1913-14, pp. 62-75).—A statement of the work of the year.

Sinuste per hour and leggard moth P. I. Parrott and H. Glascow (News)

Sinuate pear borer and leopard moth, P. J. Parrott and H. Glasgow (New York State Sta. Circ. 44 (1915), pp. 3, pls. 2).—This circular gives brief descriptions of the sinuate pear tree borer and leopard moth, which, as shown by a recent survey by the station, are being distributed into the fruit-growing sections of the State by importations of nursery stock.

Destruction of prickly pear through the agency of parasitic insects, J. WHITE-HANEY (Ann. Rpt. Dept. Pub. Lands Queensland, 1914, pp. 81-83, pls. 3).—This account relates to the propagation of wild cochineal insects (Coccus indicus from Ceylon and C. confusus capensis from South Africa). See also work previously noted (E. S. R., 34, p. 549).

The insect enemies of vegetables, J. Kindshoven (*Flugschr. Deut. Landw. Gesell.*, No. 13, 4, ed. (1915), pp. 16–27).—In this edition (E. S. R., 27, p. 438) a brief summarized account is given of the more important insect enemies of vegetables in Germany and means for their control.

Insects attacking cabbage and allied crops in Connecticut, W. E. BRITTON and Q. S. Lowry (Connecticut State Sta. Bul. 190 (1916), pp. 3-23, figs. 17).—Brief popular accounts are given of the more important enemies of crucifers occurring in Connecticut.

Insects affecting the sugar cane in Trinidad, F. W. Urich (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 5, pp. 156-161).—The author has compiled the present list of sugar cane insects with the object of providing a handy reference to these pests, their natural enemies, and methods of control.

The insect enemies of strawberries, A. Tullgren (Trädgården [Stockholm], 14 (1915), No. 6, pp. 167-169, figs. 2; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 11, p. 695).—A brief account of the enemies of strawberries in Sweden.

Cranberry insect investigations in 1914, H. B. Scammell (*Proc. Amer. Cranberry Growers' Assoc.*, 45 (1914), pp. 12-17).—The work of the year is briefly reviewed.

Some inhabitants of the round gall of golden-rod, Chi Ping (Jour. Ent. and Zool., 7 (1915), No. 3, pp. 161-179, figs. 20).—The inhabitants of round galls which occur commonly on only one species of golden-rod (Solidago-canadensis), here dealt with, include Eurosta solidaginis, the gall-making fly; the larvæ of the mordellid beetle Mordellistina unicolor; and several other occupants, three of which are parasites and the rest of uncertain position. A tabular statement of the inhabitants of 3,300 galls is included and a bibliography of 17 titles is appended.

Destructive grasshoppers in Costa Rica, A. Alfaro (Reprint from Rev. Ed. San José, Costa Rica, 1915, Oct., p. 7, fig. 1; abs. in Ent. News, 26 (1915), No. 10, p. 447).—An account is given of the invasion of Costa Rica by locusts (Schistocerca paranensis and S. zapoteca) during 1915.

The control of locusts in eastern Canada, A. Gibson (Canada Dept. Agr., Ent. Branch Circ. 5 (1915), pp. 8, figs. 6).—A brief discussion of the destructive species and control measures therefor.

On the destruction of locusts by cultures of the d'Herelle bacillus, S. S. Merezhkovskii (*Trudy Selsk. Khoz. Bakt. Lab.*, 4 (1913), pp. 368, 369).—In experiments made with the d'Herelle bacillus obtained from the Pasteur Institute in Paris, the Pasteur Institute in Algiers, and Argentina it was found that from three to six types were represented. The author recommends that the pathogenic properties of the organism at hand be determined before cultures are used in practical work.

Injury to cereals by Ælia rostrata, R. Rodriguez v Martin (Bol. Agr. Téc. y Econ., 6 (1914), No. 70, pp. 934-943, figs. 8).—This hemipteran, commonly known as "San Pedrito," is the source of considerable injury to wheat in Spain.

Chermes injurious to conifers, N. A. CHOLODKOVSKY (Khermesy, Vredushchie Khoinym Derev'ium. Petrograd: Dept. Agr. Central Bd. Land Admin. and Agr., 1915, 2. rev. and enl. ed., pp. 89, pls. 7, figs. 6; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 10, pp. 592-599).—An extended account.

Plant lice or aphids, H. A. Gossard (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 108-114, figs. 6).—This is a popular account of the life history and habits, reproduction, natural enemies, nature of damage, and means of combating plant lice.

Aphididæ of California, XI, E. O. Essig (Jour. Ent. and Zool., 7 (1915), No. 3, pp. 180-200, figs. 9).—In this paper, the eleventh of a series of articles (E. S. R., 28, p. 452), the author considers a new Lachnus (L. glehnus n. sp.) which injures the Japanese dwarf silver spruce (Pieca glehni) at Sacramento, Cal., the manzanita leaf-gall aphis (Phyllaphis coweni), and the cloudy-winged oak aphis (Callipterus bellus).

The army worm (Cirphus [Leucania] unipuncta), A. Gibson (Canada Dept. Agr., Ent. Branch Bul. 9 (1915), pp. 34, figs. 19).—A summarized account of the fall army worm, its life history and habits, natural enemies, and methods of control.

A detailed account is given of the 1914 outbreak in eastern Canada, as the result of which the loss in Ontario alone amounted to more than \$250,000. The parasites reared during the course of the outbreak include four tachinids (Winthemia quadripustulata, Phryxe [Exorista] vulgaris, Phorocera [Euphorocera] claripennis, and Wagneria [Phorichata] sequax); four braconids (Apanteles militaris, Apanteles sp., A. limenitidis, and Metcoris communis); and six ichneumonids (Paniscus geminatus, Pimplidea pedalis, Ichneumon canadensis, I. laetus, I. jucundus, and I. leucania).

Some notes on the Catalina cherry moth, E. J. Branigan (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 1, pp. 35, 36, figs. 2).—The fruit of the Catalina cherry (Prunus integrifolia) at Sierra Madre in Los Angeles County, Cal., was found to be badly infested with the larvæ of Mellissopus latiferreana, a moth which closely resembles the codling moth. "The infestation was very heavy. The larva works both in the meat of the fruit and within the seed itself, which is comparatively very large, occupying three-fourths of the inside of the cherry. The cherry averages about the size of the cultivated species of cherry. The larva seems to have a preference for the seed, the shell of which is not very hard."

Statistics on the production of silk in France and elsewhere (Statistique de la Production de la Soie en France et a l'Etranger. Lyon: Syndicat de l'Union des Marchands de Soie de Lyon, 1915, pp. 84).—Statistical data including the year 1913 relating to silk production are here presented under the

headings of occidental Europe, the Levant and central Asia, and the extreme Orient.

The biology of the North American crane flies (Tipulidæ, Diptera).—IV, The tribe Hexatomini, C. P. ALEXANDER (Jour. Ent. and Zool., 7 (1915), No. 3, pp. 141-160, flgs. 17).—A continuation of the work previously noted (E. S. R., 33, p. 561).

The bionomics of the Maltese phlebotomi, P. J. MARETT (Brit. Mcd. Jour., No. 2848 (1915), pp. 172, 173).—In this report of studies of the life history and habits of wild and tame Papatasii flies, which are of importance because of their transmission of disease, data are included on the length of the several life stages, including the pregnancy stage, egg stage, first larval and total larval stages, pupal stage, and length of life. A fungus, which is pathogenic to the fly, is provisionally termed Empusa papatasii.

Directions for combating the olive fly (Dacus oleæ), A. Berlese (Istruzioni per Combattere la Mosea delle Olive (Dacus oleæ). Florence: Min. Agr. Indus. e Com., 1915, pp. 11, figs. 8).—A summary of control measures.

The book of the fly, G. H. HARDY (London: William Heinemann, 1915, pp. [8]+124, figs. 224).—This account of the house fly includes chapters on identification, structure, life history, economic importance, methods of control, etc. Miscellaneous data relating to flies, including the Windgate fly chart with index to terms and symbols, a list of families with descriptive notes and references, an analytical table of families, etc., are appended.

The cane grubs of Australia, A. A. GIRAULT and A. P. Dodd (Bur. Sugar Expt. Stas. Queensland, Div. Ent. Bul. 2 (1915), pp. 60; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 8, pp. 490, 491).—The authors here present a detailed report of studies of the various phases in the life history and habits at Gordonvale, Queensland, of scarabæid larvæ attacking sugar cane. A preliminary report of the work by Girault has been previously noted (E. S. R., 33, p. 750).

A mission to Java in quest of natural enemies for a coleopterous pest of bananas (Cosmopolites sordida), F. P. Jepson (Dept. Agr. Fiji Bul. 7 (1914), pp. 18, pls. 3).—Following a brief account of the life history of the banana borer (C. sordida), its natural enemies are considered.

The author found several insects to prey to a greater or less extent on the banana borer in Java, of which a histerid beetle (*Plæsius javanus*) was the most important. In captivity the adult of this beetle consumed eight full-grown larvæ of the banana borer per head per diem, while its larva took no less than 33.3 full-grown larvæ per head per diem, or an equivalent in bulk of about 17 times its own size.

Five thousand of these beetles were transported in moist earth without food from Java to Fiji, and 3,792 were successfully landed at Suva, the remainder perishing, chiefly, it is believed, owing to the cold weather experienced on the coast of Queensland. Lots of 500 were distributed among seven different plantations in badly infested banana districts and 292 retained for observation. The beetles were alive and reproducing after four months, which points to their being probably established. Beetles sent from Java to Fiji by post, packed in damp moss, also arrived alive, so that there should be no difficulty in obtaining a further supply from Java if necessary.

The Colorado potato beetle (Leptinotarsa decemlineata), H. SCHABLOWSKI (Ztschr. Pflanzenkrank., 25 (1915), No. 4, pp. 193-203, pls. 3, fig. 1; abs. in Möller's Deut. Gärt. Ztg., 30 (1915), No. 42, pp. 335, 336, figs. 2).—An account is given of the appearance of this pest in Germany in 1914 and the manner in which it was eradicated.

Rice borers in Java, K. W. Dammerman (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten No. 16 (1915), pp. 71, pls. 7, figs. 2).—Five species of rice borers are known at the present time in Java, namely, Schoenobius bipunctifer, Scirpophaga scricea, two species of Chilo, and Sesamia inferens. S. bipunctifer, which occurs throughout Java, and S. scricea, found principally along the north coast and the more common there of the two, are the two most important. Of the several parasites attacking rice borers, Trichogrammatoidea nana alone may destroy as high as 60 per cent of the eggs. The destruction of the borers which remain in the stubble after harvest by deep plowing is the most effective control measure.

A note on the western twig borer, H. S. SMITH (Mo. Bul. Com. Hort. Cal., 4 (1915), No. 12, pp. 572, 573, fig. 1).—Polycaon confertus has become a pest of considerable importance in California.

The wheat straw worm (Isosoma grande), R. W. DOANE (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 2, pp. 69-72, figs. 2).—This pest has been found to be the source of considerable injury in northern California, actual counts of hundreds of wheat stems showing 84 per cent to be infested with one or more larvæ or pupæ of this insect.

Hen fleas (Xestopsylla gallinacea), J. F. Illingworth (Hawaii. Forester and Agr., 12 (1915), No. 5, pp. 130–132).—An account of the hosts, distribution and life history, and control measures for the hen flea, which appears to be a recent arrival in Hawaii, not having been collected by entomologists prior to 1913.

Notes on the habits and control of the chicken flea (Echidnophaga gallinacea), J. F. Illingworth (*Jour. Econ. Ent.*, 8 (1915), No. 5, pp. 492-495).—A report of studies, a brief account of which has been noted above.

Observations on the preoviposition, oviposition, and incubation periods of Dermacentor nitens in Panama, L. H. Dunn (*Ent. News, 26 (1915*), *No. 5*, pp. 214-219).—A report of biological studies of the tropical horse tick.

Sarcophaga fuscicauda, an intestinal parasite of man, A. Eysell (Arch. Schiffs u. Tropen Hyg., 19 (1915), No. 1, pp. 2-7, figs. 4).—Descriptions are given of the larva, pupa, and adult of S. fuscicauda taken at Tsingtau.

FOODS-HUMAN NUTRITION.

The milling and baking quality and chemical composition of wheat and flour as influenced by different methods of handling and storing, heat and moisture, [and] germination, C. O. SWANSON, L. A. FITZ, and LEILA DUNTON (Kansas Sta. Tech. Bul. 1 (1916), pp. 83, pls. 22).—The object of this investigation was to determine the effect of different methods of harvesting, stacking, and storing wheat; the aging effect of tempering with moisture and heat; and the effect of germination of new wheat on the milling quality of the wheat, the baking quality of the flour, and the chemical composition of the wheat and flour.

"All the tests were made on the same original lot of wheat. A 10-acre field of fairly uniform character was obtained. One acre was cut at the beginning of the hard-dough stage, one when the wheat was dead ripe, and the rest when the wheat was in prime condition. As soon as the wheat was dry, a few bushels were thrashed from the early and from the late cuttings, and 35 bu. from that cut in prime condition. Samples of the wheat from the three cuttings were taken to the laboratory for immediate milling, baking, and chemical tests. The wheat cut in prime condition was used for the study of the effect of germination, the process of sweating in the bin, and for treatments with heat and water. The larger part of the 10-acre field was stacked. One acre was allowed to stand in the shock."

In each series of experiments chemical analyses and milling tests were made of the wheat subjected to different treatments, as well as chemical analyses and baking tests of the flours milled from the wheat. Temperature and moisture observations were made in the storage experiments.

In the experiments to determine the aging effect of tempering with moisture and heat, the authors studied the effects of adding different amounts of water to the wheat and heating it to different temperatures for varying periods of time. These experiments showed that "heat, especially when used on new wheat, improves the milling quality of the wheat and the baking qualities of the flour. The interval that should elapse between the time the wheat is moistened and heated and the time that it is milled depends on the hardness of the wheat and the amount of moisture added. If the wheat has nearly the normal moisture content and is of good quality this 'curing' process does not seem to be so important. But where a large amount of moisture needs to be added it seems that this longer tempering is very beneficial. This was shown in the previous experiments. The miller should have at his command such facilities that he can treat the wheat with successive amounts of moisture, heat the wheat to any desired temperature, and allow it the necessary period of 'curing' before milling. . . .

"These experiments were conducted on a small scale. Investigations more nearly approximating commercial tempering conditions are needed to corroborate the results."

"The results show that it is entirely possible to treat new wheat with moisture and heat and bring about an improvement in the milling quality similar to the natural aging of the wheat. The results of the experiments on heating wheat show that the degree of heat used for destroying mill and stored-grain insects does not in any way injure the wheat or the flour."

From the results of experiments on the effect of germination of wheat, in which baking tests were made with blended flours containing varying percentages of flour from germinated wheat, it is concluded that "the claims made in regard to the damage upon the milling and baking quality of wheat and flour from such wheat, when mixed with sound wheat, have been much exaggerated. Germination injures the milling quality of the wheat in that the flour yield is less and the flour is likely to have an inferior color. The injury is in proportion to the amount of germination. The gluten of flour from germinated wheat is weaker than the gluten from flour of sound wheat. A small amount of flour from germinated new wheat when mixed with flour from sound wheat has little or no deleterious effect on the baking qualities of the mixed flour when the same general methods of baking are followed as were used in these tests."

Digestion experiments with flour containing specially prepared bran, O. VON CZADEK (Ztschr. Landw. Versuchsw. Oesterr., 18 (1915), No. 11, pp. 613-622).—Bran prepared by the so-called Finkler process of milling, using special machinery in the presence of water containing lime and salt, was found to be exceptionally well utilized by the human body. Bread was made by the addition of 15 to 20 per cent of the finely milled bran to flour milled in the ordinary way, and this was eaten by two normal human subjects as a part of a simple mixed diet. The so-called "final" bread possessed a good taste and remained in a fresh and appetizing condition longer than ordinary rye bread. From the results of comparative digestion experiments the author concludes that bread made to contain from 15 to 20 per cent of bran has practically the same nutritive value as rye bread.

The preservation of corn meal, A. Marbach (Österr. Chem. Ztg., 18 (1915), No. 11, p. 96).—In the author's opinion Indian corn meal can be preserved satisfactorily by germination previous to milling.

Indian corn for bread making, J. Bruderlein (*Bul. Soc. Bot. Genève*, *2. ser.*, 6 (1914), *No.* 5, pp. 139, 140).—A preliminary report of experiments to utilize micro-organisms of the Mucor group as leavening agents for corn bread.

The nutritive value of whole Indian corn bread, F. RÖHMANN (Berlin. Klin. Wchnschr., 53 (1916), No. 5, pp. 105, 106).—A summary and digest of data concerning the advantages of milling the entire kernel of grain for use in human nutrition.

The use of durra in human nutrition, G. TROPEA (Bol. R. Giard. Colon. Palermo, 2 (1916), No. 4, pp. 243-250).—Analytical data are reported giving the comparative composition of samples of flour made from wheat, durra, feterita, and potatoes. In the author's opinion, durra possesses a nutritive value equal in some respects to wheat flour and infinitely superior to potato flour. The use of one part of durra flour to three parts of wheat flour is advocated for bread making.

Increasing the supply of bread materials, S. THELER (Centbl. Zuckerindus., 23 (1915), No. 20, pp. 457, 458).—Baking experiments are described from which the author concludes that raw beet sugar and sugar-beet flour may both be used as additions to rye flour for bread making. The bread is said to be palatable, satisfying, and of good keeping quality.

The estimation of potatoes in war bread, W. Herter (*Chem. Ztg.*, 39 (1915), No. 88-89, pp. 555, 556).—The percentages of potato starch found in several samples of war bread are reported.

Experiments with straw bread, G. Wöllstädt and W. Kleberger (Fühling's Landw. Ztg., 65 (1916), No. 1, pp. 27-32).—Baking tests are described with mixtures of varying proportions of rye flour and finely milled oat straw. The bread was heavy and unsatisfactory. Digestion experiments of six weeks' duration also indicated that straw bread is an undesirable food, as evidenced by the facts that physiological disturbances were noted and the subjects (men) lost weight.

Concealing the use of blood in bread, R. Droste (Chem. Ztg., 39 (1915), No. 100-101, p. 634).—The use of hydrogen peroxid instead of yeast or baking powder is advocated for making bread to which blood is added. The oxygen which is set free both raises and bleaches the bread. The blood should first be kept in a refrigerator for from 24 to 36 hours, after which the serum is filtered off and added to the dough.

Skim milk and potatoes as a meat substitute, T. Pfeiffer (Wiener Landw. Ztg., 65 (1915), No. 46, pp. 366, 367).—Data are given showing the economy that may be effected by the use of skim milk and potatoes as a meat substitute. The protein content and calorific value of 4.5 liters of skim milk and 1.1 kg. of potatoes, it is stated, are equal to those of 1 kg. of beef.

Examination of Scallops, A. L. Sullivan (Amer. Food Jour., 10 (1915), No. 9, pp. 472, 473).—Analytical data are reported from which the author concludes that the practice of soaking scallops lowers the food value of the product and makes the consumer pay for a large excess of water.

Hydrocarbons in fish-liver oils, H. Mastbaum (Chem. Ztg., 39 (1915), No. 139-140, p. 889).—The author noted that certain fish-liver oils contained from 80 to 90 per cent of unsaponifiable oil. He considers the presence of mineral-like oils in fish of particular importance as evidence in support of the theory that the deposits of mineral oils on the earth originated from fish residues.

Sources of fat, O. Neuss (*Umschau*, 19 (1915), No. 49, pp. 965-967, fig. 1).— The author describes some comparatively uncommon sources of edible fat which may be utilized if necessary. Among these are hemp, poppy, and mustard seeds, hazel and beech nuts, and the stones of certain fruits like the peach.

The utilization of fruits and vegetables, Kochs (Landw. Jahrb., 46 (1914), Ergünzungsb. 1, pp. 45-50, figs. 2).—In this report directions are given for the preparation of a number of fruit and vegetable products, among them rhubarb juice, rhubarb-apple jelly, jelly from Japanese quinces, and some banana preparations.

Losses and other chemical changes in boiling vegetables, Katharine I. Williams (*Chem. News, 113 (1916*), *No. 2940*, *pp. 145-147*).—A summary and digest of data, most of which has been noted from other sources.

Nutritive yeasts as food, P. Schrumpf (München. Med. Wchnschr., 63 (1916), No. 8, pp. 269, 270).—A summary and digest of data.

Effect of storage on moisture content of cloves, A. W. Ogden (Amer. Food Jour., 10 (1915), No. 9, p. 474).—The average loss in weight of whole cloves during storage was found to vary from 2.42 per cent for a 6 months' period to 4.7 per cent for a period of 54 months.

The influence of the seasons on the toxicity of egg albumin fed to white rats, F. Maignon (Assoc. Franç. Avanc. Sci., Compt. Rend., 43 (1914), pp. 553, 554).—In the experiments here reported the animals fed during the winter on egg albumin with the addition of mineral salts died in about three weeks with a loss of more than 40 per cent of their body weight. Similar experiments in spring and autumn resulted in the death of the animals in three or four days with the loss of only 20 to 22 per cent of their body weight; these animals appeared to have died of nitrogen intoxication. It is suggested that the frequency of certain epidemics in spring and autumn may be due to a lowered resistance of the organism at that time and greater sensitiveness to nitrogen intoxication.

Is it hygienic to use apricot and peach kernels in the preparation of marchpane? K. B. Lehmann (Chem. Ztg., 39 (1915), No. 91-92, pp. 573-575).—Analytical data are given comparing the amounts of the bitter principle in the apricot, peach, and almond. The author concludes that apricot and peach kernels may be used in the place of almonds for confections, provided they are soaked in water at 50° C. (122° F.) for several hours to reduce the benzaldehyde content below 40 mg. per 100 parts of the confection.

The presence of tin in canned foods, P. Carles (Ann. Chim. Analyt., 20 (1915), No. 10, pp. 216-219).—The quantity of metal dissolved from tin containers is said to vary according to the amount of sodium chlorid present, the acidity of the medium, the surface area of the exposed tin, and the duration of contact.

[Food and drug inspection], F. H. FRICKE (Ann. Rpt. Food and Drug Comr. Missouri, 1915, pp. 59).—The report of the state chemist, H. E. Wiedemann, contains the results of the examination of 1,259 samples of foods, of which 1,000 were found to be in accordance with existing standards. The reports of the state inspectors contain the results of sanitary inspections of groceries, bakeries, and other establishments where foods are prepared and sold.

[Food and drug inspection and analysis], E. F. Ladd and Alma K. Johnson (North Dakota Sta. Spec. Bul., 4 (1916), No. 2, pp. 33-64).—This bulletin reports the results of the inspection of a number of restaurants, hotel kitchens, bakeries, confectionaries, meat markets, and slaughterhouses, made in various parts of the State during the year 1915, the score of each place inspected being given. The results of the examination of a few samples of foods and drugs, including toilet soaps, are also reported.

Twelfth annual report of the food commissioner and state chemist, E. F. LADD ET AL. (North Dakota Sta. Rpt. 1915, [pt. 2], pp. 25).—The work carried

on under the state food and drug laws during the fiscal year ended June 30, 1915, is summarized briefly. Miscellaneous information regarding pure food topics, food standards, and definitions being included.

National Association of Master Bakers (Nat. Assoc. Master Bakers [Proc.], 18 (1915), pp. 189, figs. 21).—In addition to the report of the business transacted during the convention a number of addresses are reprinted, among them the following: The Effects of the Mineral Salts Contained in Natural Waters upon the Fermentation of Bread, by H. A. Kohman; Flavor in Bread, by A. C. Junge; How the State University Can Help the Baker, by R. M. Allen; and Mill Streams and Commercial Flours, by L. A. Fitz.

A scale for marking nutrition, F. A. Manny (School and Soc., 3 (1916), No. 56, pp. 123, 124).—The scale discussed here is the one used by the Bureau of Child Hygiene for the examination of children in the New York City schools.

Food for young children, Caroline L. Hunt (U. S. Dept. Agr. Farmers' Bul. 717 (1916), pp. 20, figs. 4).—This publication is written especially for mothers and contains a short discussion in simple terms of the food requirements of children between the ages of 3 and 6 years. The foods making up the diet are classed in five groups, as follows: Milk and other protein foods; bread and other cereal foods; butter and other wholesome fats; vegetables and fruits; and simple sweets; and it is stated that a child should receive at least one food from each of these groups every day. Recipes and suggestions for the preparation of the foods in each group are given.

The feeding and care of the baby (Bul. Bd. Health Maine, 4 (1916), No. 2, pp. 40).—A popular bulletin containing information regarding breast and bottle feeding, diet during the second year, and the general care of the baby.

Casein-milk feeding in infancy and childhood, W. Gellhorn (*Jour. Amer. Med. Assoc.*, 65 (1915), No. 10, pp. 853-855).—Data comparing the composition of casein milk and other milks are reported together with a number of clinical observations, from which the author concludes as follows:

"Casein-milk feedings have been found to be successful as temporary food in allaitement-mixte and whenever it was necessary to wean a very young child abruptly. Although they do not seem to produce any harm during prolonged use, the advantages they offer are not sufficiently clear to recommend their substitution for the ordinary milk modifications in normal children.

"They can not replace breast milk in some of the severest cases, but in the great majority of nutritional disturbances, as seen in private practice, they will be found to be of assistance. They are indicated in disorders of a fermentative origin, and can be fed here in rapidly increasing doses, regardless of the stool picture, provided the child does not develop symptoms of alimentary intoxication. Through their use may be avoided the prolonged or repeated therapeutic hunger periods with their deteriorating influence on the child's organism, which are so frequently the cause of turning an originally mild into a serious disorder."

The mineral nutrients in practical human dietetics, E. B. Forbes (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 123-128).—In this article considerable important information is brought together regarding the minerals supplied to the body by different food materials.

In discussing the general mineral requirements of the body the author takes up certain special phases of the question, among them the mineral requirements of infants, including infant diseases due to mineral supply and the mineral requirements during periods of growth, reproduction, and old age. It is pointed out that liberal and diverse diets are most likely to supply a sufficient quantity of each of the minerals, and that "the central features of improperly chosen diets are usually an undue dependence upon meats and foods made from finely

milled cereals or other cereal foods lacking the outer seed coats and too little use of milk and vegetables."

Fluorin in the vegetable kingdom, A. GAUTIER and P. CLAUSMANN (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 3, pp. 105-112).—Analytical data are given showing the quantities of phosphorus and fluorin found in many different kinds of vegetables. The following amounts of fluorin, in milligrams, were found present in 100 gm. of the dry substance: The pulp of apple, 0.21; the skin of apple, 2.78; the pulp of banana, 0.38; the skin of banana, 5.1; wheat flour, 1-1.41; rye flour, 0.6; buckwheat flour, 2.53; barley, 2.2; rice, 0.94; white beans, 2.1; lentils, 1.8; mustard, 1.58; chocolate, 1.78; and green coffee, 1.45.

Further studies of nitrogen metabolism, E. Abderhalden (Hoppe-Scyler's Ztschr. Physiol. Chem., 96 (1915), No. 1-2, pp. 1-147).—The results are reported of an extensive investigation of the nutritive value of amino-acid mixtures, some of which were derived from naturally occurring protein and some from sources foreign to animal tissue. The biological value of tryptophan, tyrosin, phenylalanin, and other amino acids was studied, and also the influence of the ingestion of potassium nitrate, ammonium salts, urea, and sodium acetate upon nitrogen metabolism. Numerous feeding experiments were conducted with laboratory animals (rats). For details of the investigation the original should be consulted.

The influence of the amino acids on the pancreatic secretion, S. Kobzarenko (Internat. Beitr. Path. u. Ther. Ernährungsstör. Stoffw. u. Verdauungskrank., 5 (1915), No. 4, pp. 434-457).—Feeding experiments with laboratory animals (dogs) are described, in which mixtures of amino acids prepared from various sources were ingested and the resultant effects on the pancreatic secretions studied. An extensive bibliography is appended.

The influence of protein feeding on the elimination of creatin in starvation, W. C. Rose (Jour. Biol. Chem., 20 (1915), No. 4, Proc., p. XIX).—Experiments with normal men indicate that the feeding of large amounts of protein causes a marked diminution in the creatin elimination during starvation. As this is not true in severe cases of diabetes or in depancreatized dogs, the author concludes that the disappearance of creatin from the urine, following protein feeding, is due to the carbohydrate metabolized from protein.

The excretion of creatin during a fast, F. D. ZEMAN and P. E. Howe (Jour. Biol. Chem., 20 (1915), No. 4, Proc., p. XVIII).—The determination of creatin in the urine of a fasting man throughout a 7-day fast showed that creatin was excreted on each fasting day in amounts comparable in most cases with those obtained in previous fasts under similar conditions.

The synthetic capability of the animal body, W. Stepp (Ztschr. Biol., 66 (1916), No. 8, pp. 350-358).—From the experimental data herein reported the author concludes that the bird and animal organisms differ, in that the body of the pigeon can do without lipoids in the diet, though not without vitamins, while the animal organism requires both of these food constituents.

Is the nutritional disease produced by lipoid starvation identical with beri-beri? W. Stepp (*Ztschr. Biol.*, 66 (1916), No. 8, pp. 339-349).—In a series of feeding experiments with laboratory animals (mice) the effect of ingesting diets deficient in either vitamins or lipoids was studied.

The conclusion is drawn that a lipoid-free diet can be made complete only by the addition of lipoids, and that it can not be made sufficient by supplying other accessory nutrients such as vitamins. Similarly, a vitamin-free diet can be made sufficient only by the addition of vitamins.

Diet and pellagra. Rabbits and hares as a possible dietary factor in combating the disease, C. W. STILES (*Pub. Health Rpts.* [U. S.], 31 (1916), No. 13, pp. 817, 818).—The author suggests the possibility of the use of rabbits and

hares as a supply of meat in districts where pellagra is prevalent and where a supply of beef, mutton, etc., is not available.

The content of some digestive ferments in the feces, H. A. Kurschakow (Internat. Beitr. Path. u. Ther. Ernährungsstör. Stoffw. u. Verdauungskrank., 5 (1915), No. 4, pp. 511-527).—Clinical observations and analytical data are reported concerning the occurrence of digestive ferments in the feces under both normal and abnormal conditions. A bibliography is appended.

Sense impression and appetite, W. Sternberg (Internat. Beitr. Path. u. Ther. Ernährungsstör. Stoffw. u. Verdauungskrank., 5 (1915), No. 4, pp. 421–433).—In this article are discussed the factors which influence appetite. The fuel value of the diet and the nutritive value of the food are not deemed the only considerations in planning the dietary. The author is of the opinion that appetite is not a function of the stomach or the digestive glands, but that it is influenced principally by the senses of sight, taste, smell, and touch—that attractiveness for the senses stimulates appetite.

The calorimeter as the interpreter of the life processes. A study of the fuel requirements of the human individual, G. Lusk (Sci. Amer. Sup., 81 (1916), No. 2097, p. 171).—In this treatise the author summarizes a great deal of experimental data, most of which has been noted from the original sources.

ANIMAL PRODUCTION.

Units of reference for basal metabolism and their interrelations, C. R. Moulton (Jour. Biol. Chem., 24 (1916), No. 3, pp. 299-320, figs. 21).—This is a further discussion of work previously reported (E. S. R., 33, p. 569).

"A simple relation has been shown to exist between the total body nitrogen and the fat-free empty weight of beef cattle. A simple relation exists also between blood weight and fat-free empty weight or between blood weight and total body nitrogen. The surface area of beef cattle is a power function of the warm empty weight, the formula for fat animals being $A=0.134~W^{\$}$ and for other animals $A=0.1186~W^{\$}$. The surface area is also a power function of the fat-free empty weight. The formula for all animals is $A=0.1034~W^{\$}_1$. The surface area is a power function of the total body nitrogen, the formula being $S=N^{\$}$. The body surface and total blood are related in a similar manner, the formula being $S=0.8~B^{\$}$.

"Since these relations have been shown to be fairly constant for animals under different conditions it would seem to make little or no difference what unit of reference is used as a measure of basal metabolism as long as the unit used has been actually measured. It would seem also that for beef cattle the desired unit of reference could be calculated with considerable accuracy if the fatness of the animal and its condition with regard to fill can be determined. In many cases, however, the amount of fill in the beef animal can be disregarded. The author has shown average variations in fill of from 2 to 4 per cent of the live weight for mature animals."

The energy consumption increases with the body weight, but not proportionally, and there are large variations. The variations in the heat consumption per kilogram of body weight are great, a 500-kg. steer consuming from 25 to 35 calories per kilogram. There is a marked tendency for the consumption of energy per kilogram to decrease with increasing weight. The variations from the average are 23.5 per cent. A tendency is also shown for the heat consumption per unit of surface area to increase as the body weight increases. This has been found to be due to the greater weight sustained by the animal

while standing and walking, the energy required for this being proportional to the weight sustained. The heat consumption per kilogram of body nitrogen is quite uniform, the extreme variation being 14 per cent of the average. The tendency is for a slight decrease in this consumption per unit of blood as the animal gets heavier, an extreme variation of 15 per cent from the average being shown.

"The smallest variations are shown in the heat consumption per unit of body surface and the greatest variations in the heat consumption per unit of body weight. Per unit of body nitrogen (protoplasmic tissue) and per unit of blood the variations are not much larger than per unit of body surface. If there is a choice of units it would seem to fall upon the surface area. Since this can easily be calculated from the body weight by the formulas proposed by the writer of this paper it would seem that this unit fits well the needs of the investigator in animal nutrition, especially with beef cattle. These conclusions are opposed to the views of Benedict [E. S. R., 33, p. 264] but are in agreement with those of Du Bois [E. S. R., 34, p. 68] and Graham Lusk."

Experimental studies on growth.—I, Methods, T. B. ROBERTSON and L. A. RAY (Jour. Biol. Chem., 24 (1916), No. 3, pp. 347-361, figs. 3).—Methods employed in experiments on the growth of mice are described by which the animals may be maintained in good health and as free as possible from zymotic disease and other deleterious factors in the environment which might conceivably exert an effect upon their growth. Improved forms of cages, food receptacles, and nest houses are described.

Rapid methods of handling and weighing large numbers of animals, and a balance especially adapted to this purpose, are also described.

A further analysis of the hereditary transmission of degeneracy and deformities by the descendants of alcoholized mammals, II, C. R. STOCKARD and G. Papanicolaou (Amer. Nat., 50 (1916), No. 591, pp. 144-177, figs. 7).— The results of experiments covering a period of five years have demonstrated on two different stocks of normal guinea pigs that "the parental germ cells may be so modified by chemical treatments that they are rendered incapable of giving rise to a perfectly normal offspring. This incapacity is probably due to modifications of the chromatin or carriers of the hereditary qualities within the germ cells, since the great-grandchildren, the F_3 generation, from the treated animals are usually more decidedly affected and injured than the immediate offspring (F_1) of the alcoholized animals. . . .

"The treatment of adult guinea pigs by an inhalation method with daily doses of alcohol through several years produces little if any noticeable effect upon the organs and tissues of the animal's body. The direct action of alcohol fumes tends to injure the respiratory mucosa and to render the cornea of the eye dull or opaque. These changes, however, do not inconvenience the animals in any perceptible way, and they remain strong and hardy and live as long and actively as the untreated guinea pigs.

"In spite of their healthy appearance the injurious influence of the alcohol inhalation is very decidedly shown by the quality of offspring to which the treated animals give rise. And the descendants of these offspring are even worse than the F₁ generation when compared with the different generations of control animals produced under identical cage and food conditions. The males seem to be more injured by the treatment than the females, taking as an index of injury the quality of their offspring and descendants. Stating it differently, the spermatocytes or spermatozoa are more sensitive to the changed chemical condition of the tissues than are the female germ cells. There is a larger proportion of degenerate, paralytic, and grossly deformed individuals descended from the alcoholized males than from the alcoholized females.

"Inbreeding tends to emphasize the alcoholic effects. This is probably due to related animals responding to the treatment in closely similar ways on account of the similarity of their constitutions. Inbreeding, as such, may be harmful. But inbreeding added to the alcohol effects produces a much worse condition in the offspring than either inbreeding or alcoholism alone could do. The data from alcoholized male lines indicate that the female offspring from alcoholic males are less viable and more frequently deformed than the male offspring. And heterogeneous matings of such male and female offspring further emphasize the same inferiority on the part of the female offspring from treated males. . . . The data from alcoholic female lines indicate that the male offspring from alcoholic females are inferior in quality to the female offspring. And heterogeneous matings of such male and female offspring further prove the inferiority on the part of the male offspring from treated mothers, . . .

"The experiments show the hereditary transmission through several generations of conditions resulting from an artifically induced change in the germ cells of one generation. And they furnish data of importance bearing upon the pathological behavior of the carriers of heredity as well as the differences in behavior between the two types of germ cells produced by an animal carrying heteromorphic chromosomes."

A list of references relating to the literature cited is included.

Composition, nutritive, and manurial values of various farm foods, C. Crowther (Univ. Leeds and Yorkshire Council Agr. Ed. [Pamphlet], 73 (1916), 3. ed., folio).—The composition and nutritive value of the following feeding stuffs is given: Egyptian and Bombay cotton-seed cakes; linseed, hemp-seed, rape, peanut, coconut, palm-kernel, and soy-bean cakes; soy beans; flaxseed; dried yeast; locust beans; wheat middlings, sharps, and bran; oatmeal; maizegerm meal; gluten meal; gluten feed; rice meal; malt; malt dust; wet brewers' grains; dried brewers' grains; dried distillers' grains; molasses; meat meal; fish meal; wheat; barley; oats; rye; maize; beans; peas; wheat, barley, rye, oat, bean, and pea straws; meadow hay; "seeds" hay; pasture grass; clover; vetches; alfalfa; cabbage; rape; turnip tops; turnips; swedes; mangels; carrots; sugar beets; potatoes; whole, skim, and separated cow's milk; whole, skim, and separated mare's milk; and whey.

Ensilage of fresh turnip leaves, H. ÅKERBERG (Tidsskr. Norske Landbr., 22 (1915), No. 8, pp. 348-354).—The leaves are placed on loose sandy soil in a ditch 6.5 meters (21.33 ft.) long, 2 meters wide at the bottom and 3.3 meters at the top, 1.2 meters deep, and holding 16,000 kg. (over 17.5 tons) of fresh turnip leaves. The ditch is lined at the bottom with boards and the sides covered with a thin layer of straw, protecting the leaves from being soiled by earth. The leaves should be as fresh as can be obtained and receive hard daily packing.

The best temperature for a good silage is from 30 to 45° C. (76 to 113° F.). Should the temperature not rise to 30°, it is necessary to wait before adding more leaves; should it reach 45°, or threaten to rise above it, it is necessary to put fresh leaves on as fast as possible and to pack them down hard.

When the leaves are well packed the heap settles slowly, and when the temperature falls to 30° it is first covered with a thick layer of straw, which in its turn is covered with earth to prevent the access of air to the silage. After a few days the temperature is taken, and should it have reached 40° or more, more earth is heaped over the first; but if 30° or less it should be left as it is until the temperature reaches the desired degree. Care should be taken that the cover of earth be uniform. In taking the daily supply of silage no more than necessary of the earth and straw covering should be disturbed.

Exposure to the air darkens the silage. In changing the feed from roots to silage some care should be taken to accustom the cows to it gradually; later, good milch cows may be given 12 kg. a day, and ordinary and young animals 6 kg.

Cattle forms found in the environs of Börssum in the Duchy of Brunswick, L. Knoop (Landw. Jahrb., 48 (1915), No. 5, pp. 791-803, figs. 6).—This is a report of a study made of the skeletal measurements, dentition, and general conformation of the remains of certain prehistoric types of cattle found in the Duchy of Brunswick, Germany.

Color in cattle, W. Graham (Live Stock Jour. [London], 83 (1916), No. 2188, pp. 177, 178).—A general discussion of the physiological aspects of color in cattle.

Are sheep profitable in Maine? C. D. Woods (Maine Sta. Bul. 246 (1916), pp. 30-36).—This is an account of the expenditures incident to the care and management of an ordinary farm flock of grade Hampshire sheep consisting of 75 ewes, 55 lambs, and 3 bucks, for one year under Maine conditions. The cost of operation for the year was \$1,306.63. The sales and inventory aggregated \$1,048.67. The total loss without any consideration of overhead charges, depreciation of plant, rent of land, interest on investment, or taxes that a farmer would pay, was \$257.76, or about \$3.45 for each of the old ewes.

Sheep feeding trials at Williston Substation, W. H. Peters and C. H. Ruzicka (North Dakota Sta. Bul. 115 (1916), pp. 301–316, figs. 13).—Two lots of range-grown Hampshire grade lambs were fed during the winter of 1914 for 103 days. Lot 1 of 50 lambs received no feed except good alfalfa hay, all they would eat; lot 2 of 220 lambs, alfalfa hay and a light grain ration composed of elevator screenings for the first one-third of the period and corn and barley for the remaining two-thirds of the time. The feeding of grain in addition to alfalfa hay practically doubled the gains for the entire period. The feeding of grain with the alfalfa increased the margin between the purchase price plus feed cost and the selling price from \$1.21 for the alfalfa lambs to \$1.76 for the alfalfa and grain lambs, or a difference of 55 cts. per head in favor of the grain feeding. The dressing percentage on the alfalfa and grain fed lambs was 53.1 per cent, and on the alfalfa-fed lot 50.3 per cent.

In a second trial a single lot of 210 lambs was fed during the fall, instead of the winter as in the first trial, for 75 days. They were allowed to run in a corn patch and later were turned into stubble fields, receiving in addition a light feed of alfalfa hay and a little grain. In November they were taken off the stubble and fed for a month a heavy grain feed consisting mainly of barley together with some refuse grain and soft corn. These lambs made an average daily gain per head of 0.29 lb. and realized a profit of \$1.72 per head. The grazing on corn and stubble proved successful and aided considerably in keeping down the cost of grain for the entire feeding period. Thirty-five days of hay and grain feeding at the close of the stubble season was sufficient to put the lambs on the market as choice butcher lambs in good killing condition.

In comparing the gain made by small and large lambs it was found that the former made the greater percentage increase by 10.17 per cent. However, when placed on the market the 15 large lambs sold at 8.65 cts. per pound and the 15 small ones at 8 cts. This fact would indicate that the small lambs, if one were buying a carload of them, would have to be bought at a lower price per pound than the large ones if as much profit were to be made in feeding them. In this trial it would have been necessary to purchase them at least 0.6 to 0.75 ct. per pound cheaper.

Suffolk sheep and what they mean (Live Stock Jour. [London], 83 (1916), No. 2188, p. 179).—A study of the breed characteristics and utility value of the

Suffolk breed of sheep, and the possibility of their introduction into Canada, Australia, Argentina, New Zealand, and other places.

The sheep in Egypt, G. C. Dudgeon and Mohammad 'Askar (Agr. Jour. Egypt, 5 (1915), No. 1-2, pp. 31-45, pls. 8).—A discussion of the breed characteristics, distribution, and utility value of the various breeds of sheep native to Egypt.

Inheritance of fertility in swine, E. N. Wentworth and C. E. Aubel (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 25, pp. 1145-1160, figs. 4).—The authors summarize the results of their studies at the Kansas Experiment Station as follows:

"Fertility in swine offers favorable material for the study of quantitative inheritance, because the units of deviation are discrete. Biometric studies of litter size with mother and daughter have indicated a small degree of inheritance. Crosses of breeds having different mean litter sizes have suggested that segregations of fecundity factors may take place. Numerous nongenetic factors limit the full expression of the inborn possibilities of fertility. Certain few somatic characters may be correlated either in a physiological or genetic manner with the different degrees of fecundity, but the bulk of characters usually assumed to be so related are probably entirely independent of it. Herdbook data on the fertility of swine present sources of error, but the percentage of error is low enough to permit the statistics to be suggestive.

"Numerous influences exist which lower the size of litter, which sources of error may operate in a manner compensatory to those just mentioned. It is questionable whether the size of litter represents the hereditary factors transmitted, but the somatic character was perforce accepted at face value in these studies. There is no reduction in variability in the litter sizes of the dams as compared with the grandparents or progeny, as would result if there were homozygous differences for fertility in the grandparents. Hence, the fertility deviations are either nongerminal or else the degree of heterozygosis is so great in the grandparents that no increased variability in the F₂ generation is possible. The latter explanation is probably the correct one. The frequency curves for the 3,540 litters studied make it appear that there are at least three centers of deviation in swine fertility. These centers possibly correspond to genetic factors involved in the inheritance of fecundity."

A bibliography of literature cited is given.

Some hog raising experiments, W. A. LINKLATER (Washington Sta., West. Wash. Sta., Mo. Bul., 3 (1916), No. 12, pp. 2-4).—Twenty newly-weaned pigs were turned on clover May 3, and 10 more on May 17. These pigs were fed a pound each of mixed grain daily as a thin slop, this grain mixture consisting of ground barley, oat middlings, and oil meal, 3:3:1. The grain mixture was gradually increased until the seventh week, after which time the pigs were fed 1\frac{3}{3} lbs. each per day. The pigs apparently did not care for the clover pasture, but gained 0.27 lb. each, daily, and required 5.37 lbs. of grain, plus the clover pasture, for each pound of gain. On July 24 the pigs were turned into grain fields of winter wheat and field peas, and had hogged off the grain clean by September 16. In that time they had gained 1,676 lbs. or a little over 1 lb. per pig per day. It is estimated that they required 3.58 lbs. of grain to produce 1 lb. of gain.

The pigs were then divided into 5 lots of 6 pigs each and fed 38 days. Lot 1 received ground barley alone; lot 2 ground barley and tankage, 9:1; lot 3 ground barley and oil meal, 4:1; lot 4 ground barley and alfalfa meal, 4:1; and lot 5 ground barley and skim milk, 1:2.5. These lots made average daily gains per pig of 1, 1.2, 1.2, 1.1, and 1.4 lbs., consuming 4.54, 3.82, 3.7, 4.1, and 2.6 lbs. of grain per pound of gain for the respective lots. Lot 5 consumed, in addi-

tion, 6.5 lbs. of skim milk per pound of gain, but made the most economical gains. The addition of protein-rich feeds as a supplement to ground barley effected a considerable saving in the amount of grain required per pound of gain.

Successful experiments are reported in feeding roots, particularly mangels, to brood sows, from 15 to 20 lbs. of raw mangels and 1 lb. of grain being fed daily. The results of hogging off mangels, ruta-bagas, kale, and rape are given, as furnished by a private farm in Washington. The hogs relished the mangels best, the ruta-bagas being eaten less readily. The hogs did not do so well on rape as they did on kale, but this was thought to be due to the dried condition of the rape.

The hogs on half rations of ground barley ate much larger quantities of roots and forage than those on a full ration, though they made only about half as large gains. Two lots of hogs on the mangels had the same acreage each and the same tonnage of mangels, approximately, but those on the half rations of grain had their mangels all eaten in 19 days, while the full-ration hogs were put back on their field again and required 11 days longer to clean up all their mangels. All the hogs on full feed were in good condition for slaughter at the conclusion of the experiment; the others were not.

Swine feeding experiments comparing skim milk, blood-grain meal, and fat-free fish-feed meal for young swine, Klein (*Milchw. Zentbl.*, 44 (1915), No. 6, pp. 81-86).—Three lots of pigs fed a basal ration of skim milk, barley, barley bran, and potato flakes, lot 2 receiving a blood-grain feed, and lot 3 fish meal in addition, made average daily gains per head per day of 0.397, 0.379, and 0.37 kg., demonstrating that these supplementary feeds have little value when skim milk forms a part of the basal ration.

Successful swine rations for the corn belt, J. M. EVVARD and W. H. PEW (Iowa Sta. Circ. 26 (1916), pp. 3-15, figs. 8).—This circular gives suggestive rations for fattening hogs, breeding sows, and suckling sows under both drylot and forage-feeding conditions.

Stallion enrollment.—IV, Report of stallion enrollment work for year 1915 with lists of stallions and jacks enrolled, H. E. McCartney (*Indiana Sta. Circ.* 53 (1916), pp. 238, pl. 1).—This is a report of stallion enrollment work for the year 1915, with lists of stallions and jacks enrolled.

Spotted asses, A. E. Jenks (Jour. Hercdity, 7 (1916), No. 4, pp. 165-168, figs. 2).—It is stated that while piebalds are common among most domesticated animals the ass, like the camel and elephant, rarely has spots. However, instances of the kind are cited and it is thought that selective breeding is largely responsible for this albinism.

Bacterial infection of hen's eggs, A. Postolka (Wiener Tierärztl. Monatsschr., 3 (1916), No. 1, pp. 3-11).—Out of 144 eggs examined 35 were found to be bacterially infected. The principal bacteria found were Bacillus mesentericus vulgatus, Staphylococcus pyogenes aureus, B. subtilis, and B. megatherium.

Care and management of baby chicks, Mr. and Mrs. G. R. Shoup (Washington Sta., West. Wash. Sta., Mo. Bul., 3 (1916), No. 12, pp. 11-16).—General methods for handling baby chicks for the first eight weeks are given.

DAIRY FARMING—DAIRYING.

The succulent feed supply, E. B. Stookey (Washington Sta., West. Wash. Sta., Mo. Bul., 3 (1916), No. 12, pp. 8-11).—Five plans for supplying succulent feed for the dairy farm the year round are given. In two of these the silo is

made use of, two depend on pasture and soiling crops, and one depends very largely on pasture.

Report of the first Jersey sires' futurity test of the Aroostook Jersey Breeders' Association, R. Pearl (Maine Sta. Bul. 247 (1916), pp. 37-52).—It is stated that the idea underlying the inauguration of the sires' futurity test was that the surest indication that anyone can have of the breeding worth or value of an animal lies in the performance of its progeny. The first sires' futurity test of the Aroostook Jersey Breeders' Association was held at Aroostook Farm, Presque Isle, Maine, November 15, 1915, under the auspices of the station. Rules and methods of conducting the test are given, together with the results in milk and fat production in the 1915 test.

Finding the prepotent sire, J. M. Hover (Jour. Heredity, 7 (1916), No. 4, pp. 173-178).—The author concludes from the study of the Guernsey advanced register that "marked prepotency is limited to a comparatively few animals; strongly prepotent sires usually belong to prepotent families or strains; prepotency is probably enhanced by inbreeding; prepotency may become a valuable aid to intelligent selection in breeding for greater production."

The causes of the beginning of milk secretion, H. Möllgaard (Mælkeritid., 28 (1915), No. 7, pp. 121-139, fig. 1).—As a result of his studies the author concludes that in the preparatory growth of the milk gland in young female animals during their first pregnancy chemical substances are secreted in the ovary. The lacteal gland during pregnancy secretes during its latter half of development certain chemical substances, apart from the progeny itself, which go into the mother's blood. The beginning of milk secretion is intimately connected with the expulsion of the progeny, and possibly separates chemical compounds which emanate from the placenta. The influence of the hypophysis is deemed of considerable indirect importance in the secretion of milk.

The preservation of milk samples for investigational purposes, J. TILL-MANS, A. SPLITTGERBER, and H. RIFFART (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 27 (1914), No. 12, pp. 893-901; abs. in Hyg. Rundschau, 26 (1916), No. 1, p. 21).—Various methods of preserving milk samples are described.

Report of the committee on standard methods for the bacterial examination of milk, M. P. RAVENEL ET AL. (Amer. Jour. Pub. Health, 5 (1915), No. 12, pp. 1261, 1262).—Methods for the bacterial examination of milk as adopted by a committee of the American Public Health Association in September, 1915, are outlined.

Counting bacteria by means of the microscope, R. S. Breed and J. D. Brew (New York State Sta. Tech. Bul. 49 (1916), pp. 3-31, pls. 2, figs. 5).—This is a continuation of work previously noted (E. S. R., 31, p. 78). The present bulletin reviews and discusses the technique involved in counting bacteria in milk and other substances by means of a microscope, giving at the same time the results of studies which have been made in order to determine the sources and the amounts of the errors in counts made in this way.

"The results obtained from the examination of samples of milk collected in clean test tubes containing preservatives indicate that just as accurate counts of the number of bacteria present can be made from such samples as can be made if the samples are collected in sterile tubes and iced. Under certain conditions this method of collecting samples may become a great convenience. Capillary pipettes have been found to be more satisfactory for the measurement of 0.01 cc. quantities of milk than standardized wire loops. Faulty calibration of pipettes has been found to be a serious cause of error. Allowance must be made for the adhesion of a certain quantity of milk to the pipette if accuracy of measurement is to be secured.

"It has been found that sterilization of pipettes is an unnecessary refinement of technique and that a single pipette may be used for making preparations from a long series of samples, provided it is carefully cleaned in glass-cleaning solutions after each day's use and also cleaned by rinsing in fresh clean tap water after using in each sample and before passing to the next sample. Carelessness in cleaning pipettes causes marked errors in counts.

"Growth of bacteria has been found to take place in the drops of milk as they dry, so that it is important that these be prepared either from samples containing preservatives or that the milk be dried quickly. No growth was detected in the dried films even after incubation in a moist, 37° C. incubator for one to four days. The claim made by some that bacteria are removed when the fat drops are dissolved by solvents does not seem to have any foundation in fact. The dried milk solids-not-fat appear to act as a practically perfect fixative, no detectable mechanical loss of bacteria taking place when the fat drops are removed. On the other hand, serious errors in count are introduced where the bacteria are stained in the milk before the dried films are prepared, because in this way the bacteria are not always sufficiently stained to make it posssible to detect the full number present. Where the fat drops are left in the films, even though these be spread out so as to be in a very thin layer, they tend to obscure bacteria and so lower the count.

"The two essential conditions for making a reasonably accurate count of small objects, like bacteria, under a microscope are that the objects themselves be prepared in such a way that they are distinctly visible and recognizable and at the same time evenly distributed over the field of the microscope. These conditions are sometimes best secured in dried films, in other cases in liquid preparations. Microscopical methods of examining dried milk films are of value for two purposes: (1) They may be used for the rapid examination of milk in order to grade it according to its bacterial quality, both the number and the character of the bacteria present being taken into account, A microscopical examination permits a fairly accurate guess as to the probable plate count which will be secured from a given sample of milk. (2) They are also useful as research methods, the microscopical method being the only known method which permits a count of the number of individual bacteria. Microscopical counts of the number of isolated individual bacteria and compact clumps present in milk give figures which compare well with those obtained where Petri plate methods of counting are used."

Sources of bacteria in milk, M. J. PRUCHA (N. Y. Produce Rev. and Amer. Cream., 41 (1916), No. 23, p. 925).—A popular discussion of the work previously noted (E. S. R., 33, p. 876).

Butter fat investigation (Georgia Sta. Rpt. 1915, p. 13).—In preliminary work by F. H. Smith it has been found that cotton-seed oil may be detected in the butter made from cows fed cotton-seed meal within 12 to 36 hours after first feeding. From the time of the first appearance the test for cotton-seed oil became more pronounced, until the seventh day, when the influence of the oil appears to be at its maximum. After two, four, and six weeks continuous feeding of oil the effect is no more pronounced, in most cases even less, than at the end of the first week. When the oil is removed from the ration its effect apparently disappears within one or two weeks. The results would indicate that the oil is not transferred directly to the milk fat, but enters the milk fat only after it has undergone some change in the animal body.

The cheese value of milk of various compositions, E. Haglund (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 116 (1915), pp. 29; K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 7, pp. 583-609).—Extensive experi-

43795°-No. 1-16-6

ments were conducted to determine the value of different kinds of milk in the manufacture of cheese.

It was found that when the percentage of fat in the milk was increased, other conditions being the same, the absolute as well as the relative loss of fat in the whey was also increased, so that in the manufacture of cheese from thin milk a larger percentage of fat goes into the cheese than when it is manufactured from richer milk,

The poorer milk gives more cheese per pound of fat than does the richer. The loss of fat in the whey can not be lowered by using warm milk immediately after milking, but the use of milk greatly chilled increases the loss to a very small extent. The loss of fat in the whey is greater in the manufacture of large-eyed cheese than in that with small eyes.

The same relative quantity of nitrogen is lost in the whey regardless of the nitrogen content of the milk. When the content of nitrogen in the milk increases the content of casein nitrogen is also increased, but this does not prove a definite relation between the contents of casein nitrogen and total nitrogen.

Indol in cheese, V. E. Nelson (Jour. Biol. Chem., 24 (1916), No. 4, pp. 533-536).—In these studies, conducted at the Wisconsin Experiment Station, "indol and phenol were found to be present in Limburger cheese. Skatol was not found in Limburger cheese. Indol is present in handkäse. It is doubtful if skatol and phenol are to be found in this type of cheese. A trace of indol is present in Camembert cheese. Skatol and phenol are absent in this type of cheese. Cheddar, Swiss, gammalost, brick, and Roquefort do not contain any indol, skatol, or phenolic bodies. The amount of indol in a Limburger cheese naturally varies, depending upon how far the ripening process has gone. A young cheese may contain such a small amount that a quantitative estimation is impossible, while a good ripe Limburger cheese may contain as much as 1 part in 52,800 parts of cheese.

"Lactic and bulgaricus forms of organisms when grown upon media containing tryptophan produced no Indol or skatol. As growing organisms upon pure amino acids is more difficult than upon proteins it may be necessary to add a little peptone or milk to the culture, and until further work has been done upon this phase it will be impossible to say that these organisms do not produce these putrefactive substances. The liquefying coccus isolated from a Cheddar cheese appears to produce traces of indol from tryptophan. If the experiments now in progress confirm this statement, then the explanation why no indol is produced by this type of organism in Cheddar cheese must be that conditions are unfavorable and growth is suppressed."

Study of the glycerin and lactic fermentation bacteria of cheese, Gerda Trolli-Petersson (Mcddel. Centralanst. Försöksv. Jordbruksområdet, No. 104 (1915), pp. 15; K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 1, pp. 30-42).—The author states that three kinds of glycerin bacteria have been discovered by her in Swedish cheese. These bacteria coagulate the milk but do not form any eyes or gas bubbles.

Experiments made with several kinds of cheese showed that *Bacterium chiecrini* (type a) forms, after long cultivation, gas in a lactose solution, while before cultivation it does not do so. It does not cause hydrolysis of fat. It is found in the Swedish-Swiss cheese, as well as in the Gouda and the Westbotten cheese (Västerbotten), and in greater quantity in the fresh cheeses than in the older ones. No change of taste could be detected when the *B. glycerini* was added to cheese milk under ordinary dairy conditions.

Several varieties of lactic fermentation bacteria were isolated from the above-mentioned cheeses, but no quantitative difference in these was detected. The number of *B. acidi propionici* in cheese 11 months old with normal formation of

eyes was small, but in cheese with larger eyes the number was greater. Cheese containing a large percentage of saltpeter developed no fermentation when inoculated with lactic nutritive solutions.

Several tables are given which show the number of glycerin bacteria and of *B. acidi propionici* in the various kinds of Swedish cheese at various stages.

VETERINARY MEDICINE.

The principles of veterinary surgery, L. A. Merillat (Chicago: Alexander Eger, 1915, 2. ed., rev. and enl., pp. 352, figs. 114).—This volume is intended to meet the requirements of the student of veterinary medicine and of the practitioner. The second part (pp. 149-345) consists of a translation of Pathologie Chirurgical Generale, by LeBlanc, Cadeac, and Carougeau.

Biological therapeutics, A. Eichhorn (Cornell Vet., 6 (1916), No. 1, pp. 5-24).—A general review of the biological products in use as therapeutic and diagnostic agents.

Immunity: Methods of diagnosis and therapy and their practical application, J. Citron, trans. by A. L. Garbat (Philadelphia: P. Blakiston's Son & Co., [1914], 2. ed., rev. and enl., pp. XVII+267, pls. 2, figs. 38).—This is the second edition, revised and enlarged, of the work previously noted (E. S. R., 27, p. 76). Chapters on tumor studies and anaphylaxis have been added to the new edition and the subject matter of chemotherapy greatly elaborated.

• A laboratory course in serum study, H. ZINSSER, J. G. HOPKINS, and R. OTTENBERG (New York: The Macmillan Co., 1916, pp. XIII+184).—This volume embraces a series of experiments and diagnostic tests in immunology carried out in an optional course given to medical and graduate students by the authors at Columbia University. Some of the subjects considered are immunization of animals; bactericidal and hemolytic power of normal serum; hemolysis; quantitative relations of amboceptor and complement; agglutinins and agglutination; precipitins; complement fixation; preparation for and technique of the Wassermann test; titration of an unknown antitoxin; animal toxins; antitrypsin; opsonins and titration of immune opsonins; and anaphylaxis.

Further researches on combined vaccines, A. Castellani (Centbl. Bakt. [etc.], 1. Abt., Orig., 77 (1915), No. 1, pp. 63-73).—This material has been previously noted from another source (E. S. R., 33, p. 477).

The origin of the antibodies of the lymph, F. C. BECHT and A. B. LUCK-HARDT (Amer. Jour. Physiol., 40 (1916), No. 2, pp. 366-371, figs. 3).—From the investigation it is concluded that "the concentration of antibodies is greater in the serum than in the thoracic lymph, and greater in the thoracic lymph than in the neck lymph, not only in the actively immune animal but also in the passively immune animal; not only after equilibrium is established, but at the time when active exchange is occurring. The source of the antibodies of the lymph is the blood by direct exchange from that fluid. There is no evidence that antibodies originate from the tissues and are emptied into the lymph stream at the seat of formation."

Studies on the Abderhalden reaction, E. Weise (Arch. Hyg., 85 (1916), No. 2-3, pp. 61-116).—From the investigation it has been demonstrated that specific ferments which cleave placenta protein can not be detected in the blood serum of pregnant swine, since such serum contains too many bodies which react with ninhydrin. The serum also shows no regularity in its action, the serum of nonpregnant animals very often cleaving placental substrate. The dialysis procedure for the determination of pregnancy in swine is, therefore, neither practicable nor reliable. In pregnant sheep and cattle placenta-protein-splitting ferments are very easily detected and are never found in nonpregnant

animals. The dialysis reaction, used in connection with clinical data, greatly facilitates the diagnosis of pregnancy.

For the determination of tuberculosis in cattle the dialysis procedure is a valuable diagnostic means, the number of failures being no larger than are yielded by the tuberculin reaction. Its practicability, however, should be further investigated.

The fixation of salvarsan and neosalvarsan by the blood after intravenous injection, W. J. Young (Biochem. Jour., 9 (1915), No. 4, pp. 479-484).—It has been shown that "after intravenous injection of goats with salvarsan and neosalvarsan the serum contains arsenic in a form which can not be separated from the proteins by dialysis, and which is precipitated with the serum proteins by tannic acid. Salvarsan and neosalvarsan behave, therefore, in a similar manner to atoxyl. No such combination is obtained when inorganic arsenic is injected. This combined arsenic is found in the blood long after all free salvarsan and neosalvarsan have been eliminated. This combined arsenic is found in the plasma and in the red blood cells, but no trace of arsenic is retained in the fibrin."

Further investigations on the identification of anthrax by the precipitation method, Schütz and Pfeller (Arch. Wiss, u. Prakt. Tierheilk., 41 (1915), No. 4-5, pp. 286-321).—Experiments extending over a period of several years have demonstrated that anthrax can be easily diagnosed by the precipitation method. For the recognition of anthrax in cattle, horses, sheep, and swine, it is deemed the most reliable of all the methods in use.

The experimental results are submitted in tabular form.

Experiments in vaccination against anthrax, A. Eichhorn (Jour. Amer. Leather Chem. Assoc., 11 (1916), No. 4, pp. 186-204).—Previously noted from another source (E. S. R., 34, p. 579).

Proceedings of a conference to consider means for combating foot-and-mouth disease, held at Chicago, Ill., November 29 and 30, 1915 (U. S. Dept. Agr., Proc. Conf. Combating Foot-and-Mouth Disease, 1916, pp. 157).—A report of the proceedings of a conference which was called and presided over by the Assistant Secretary of Agriculture, C. Vrooman, who, in the opening statement, briefly reviewed the general situation.

The addresses delivered are as follows: The Application of Quarantine to Public Stock Yards and What Restrictive Measures Should Be Employed to Prevent the Infection of Such Yards Which So Far as Possible Shall Not Burden Traffic, by J. S. McFadyen (pp. 9-18); What Should Be Done to Improve the Control of Cleaning, Disinfection, and Movements of Stock Cars Used for Animals Originating in Quarantined Areas? by T. W. Tomlinson (pp. 18-28); An Ideal State Law for Cooperation Between State and Federal Authorities in Work of Eradicating Contagious Animal Diseases, by C. J. Marshall (pp. 29-38); What General and What Specific Rules Should Be Observed in Fixing the Periods and Duration of the Different Forms of Quarautine Against Foot-and-Mouth Disease? by V. A. Moore (pp. 39-46); The Need for Legislation Providing for Full Compensation, Effective Quarantine, and Saving Pedigreed Stock, by M. D. Munn (pp. 46-55); Economic Effect on Dusiness Men as Well as Farmers of Temporary Outbreaks and of Permanent Presence of Live Stock Disease, by A. J. Glover (pp. 55-61); Remarks by Dr. J. G. Rutherford (pp. 62-67); discussions on losses from quarantine restrictions (pp. 67-78), probable origin of the outbreak (pp. 78-80), payment for losses in Illinois (pp. 80-82), and spread of foot-and-mouth disease by contaminated autihor-cholera scrum (pp. 82-87); The Economic Importance to Stock Yards of the Eradication of Foot-and-Mouth Disease, by A. F. Stryker (pp. 87-89); Quarantine Zones or Units, by J. I. Gibson (pp. 89-106); The Cause of Footand-Mouth Disease, by V. A. Moore(pp. 106-111); Disease Eradication and Live Stock Loans, by B. F. Harris (pp. 111-114); The Agricultural Press and Foot-and-Mouth Disease, by H. Wallace (pp. 114-132); Uniformity in Federal and State Laws and Regulations, by F. A. Balser (pp. 132-142); and Methods of Eradicating Foot-and-Mouth Disease, by J. R. Mohler (pp. 143-149).

Foot-and-mouth disease in man, R. L. Sutton and A. O'Donnell (Jour. Amer. Med. Assoc., 66 (1916), No. 13, pp. 947-949, figs. 5).—The history and pathology of a case of the disease in man are reported in detail.

Active immunization against glanders, A. Marker (Arch. Wiss. u. Prakt. Tierheilk., 41 (1915), No. 4-5, pp. 272-285).—The earlier attempts of active immunization against glanders are reviewed and briefly discussed, and the author reports experimental results obtained by Levy, Blumenthal, and himself in which a suspension of bacteria killed by 80 per cent glycerol was used as a vaccine.

In the case of guinea pigs one large injection was sufficient to protect the animals against a subsequent infection. The same results were obtained with horses which, however, received two injections at an interval of two weeks.

Similar results were obtained using a vaccine prepared from bacilli killed with a solution of urea. This preparation has an advantage in that it can be preserved in powdered form, thus preventing a further attenuation of the bacilli, and can be easily prepared when desired for use. Actual field tests covering a period of four years, in which more than 1,000 horses were vaccinated, seemed to demonstrate conclusively the value of such a vaccine, especially where glanders is likely to be carried into noninfected regions.

See also a previous note by Levy et al. (E. S. R., 18, p. 773).

Leishmaniasis in animals, A. LAVERAN (Ann. Inst. Pasteur, 28 (1914), Nos. 9-10, pp. 823-838; 11-12, pp. 885-912; 29 (1915), Nos. 1, pp. 1-21, fig. 1; 2, pp. 71-104, pls. 2, figs. 2; abs. in Jour. Compar. Path. and Ther., 28 (1915), No. 3, pp. 243-246).—In this paper the author deals with the subject as follows: (1) Natural leishmaniasis in the dog; (2) infection set up experimentally with Leishmania infantum; (3) infections set up experimentally with L donovani; and (4) natural and experimental infections with L. tropica.

The Negri bodies in some animals which hibernate and their relation to the Negri bodies of other animals, F. Sanfelice (Ztschr. Hyg. u. Infektions-krank., 79 (1915), No. 3, pp. 452-491, pls. 4).—The author reviews the literature on the subject, and discusses the course of rabies and occurrence of Negri bodies in the European hedgehog (Erynaceus curopœus) and in the European dormouse (Muscardinus avellanarius), Negri bodies in some nonhibernating animals and in birds, and the origin of inclusion bodies.

Inhibitory properties of magnesium sulphate and their therapeutic application in tetanus, S. J. Meltzer (Jour. Amer. Med. Assoc., 66 (1916), No. 13, pp. 931-934).—The author briefly discusses the theory of the inhibitory properties of magnesium sulphate and describes the methods used in its administration in tetanus.

Tuberculosis in the dog and cat, W. R. Blair (Cornell Vet., 6 (1916), No. 1, $pp.\ 25-35$, $pls.\ 2$).—The author outlines in detail the symptoms and lesions of tuberculosis in the dog and cat, and reports nine cases in the dog, together with the autopsical findings. The use of tuberculin as a diagnostic agent in such animals is deemed by the author not to lead to any reliable conclusions.

Graphic charts (Roy. Com. Tuberculosis, Final Rpt., II, App., 7 (1912), pp. 57. pls. 51).—This report illustrates graphically some of the results of the investigations of the Royal Commission on Human and Animal Tuberculosis, from 1902 to 1910. Detailed references are made from the charts to previous

volumes of the report of the commission which describe the work in detail. See also previous notes (E. S. R., 26, p. 884; 30, p. 283).

Monascus purpureus not a causative factor in forage poisoning, L. R. HIMMELBERGER (Jour. Compar. Path. and Ther., 28 (1915), No. 3, pp. 185-190, fig. 1).—Studies carried on by the author in connection with investigations previously noted (E. S. R., 34, p. 681) have led to the following conclusions:

"M. purpureus grown under laboratory conditions had no etiological significance in this outbreak of forage poisoning, since feeding large quantities over sufficient lengths of time did not produce the disease. We desire to present the evidence of the foregoing experiments as suggestive of the nonpathogenicity of M. purpureus when fed in large quantities and when the products of its metabolism are injected intravenously.

"I. purpureus isolated from oats which had undoubtedly given rise to forage poisoning in horses and mules did not produce soluble or extracellular toxins in vitro on the cultural media employed, as shown by absence of clinical symptoms

in the experimental animals."

Investigations on the intestinal flora of healthy oxen, A. FISCHER (Centbl. Bakt. [ctc.], 1. Abt., Orig., 77 (1915), No. 1, pp. 6-39, fig. 1).—The intestinal flora in mature animals, in calves from three to five months old, and in fasting calves (from a few hours to several days old) were studied. The effect on the flora of pasture feeding, winter feeding, and milk feeding was also studied.

The cultural, morphological, and biochemical characteristics, together with the pathogenicity, in some cases, of 38 organisms isolated are submitted.

A bibliography is appended.

Contagious abortion in cattle in Ehodesia, L. E. W. Bevan (Jour. Compar. Path. and Ther., 28 (1915), No. 2, pp. 97-104).—A report of investigations of this disease which have been carried on in Rhodesia, where cases of abortion in domestic stock have been reported from time to time during the past ten years.

Coccidiosis in cattle and carabaos in the Philippine Islands and its relation to rinderpest, C. H. SCHULTZ (Jour. Amer. Vet. Med. Assoc., 48 (1916), No. 6, pp. 687-705).—Substantially noted from another source (E. S. R., 33, p. 482).

The distribution and abundance of the ox warbles, Hypoderma lineata and H. bovis, in the United States, F. C. BISHOPP (Ann. Ent. Soc. Amer., 8 (1915), No. 4, pp. 359-364, fig. 1).—H. lineata is said to occur in every State in the Union, although there is considerable difference in its abundance in different sections. H. bovis is rather widely distributed through the northern part of the United States, the Northeastern States having by far the greatest infestation, and it predominates over H. lineata in both distribution and abundance. In the western two-thirds of the country it is found in rather restricted and well-separated areas. A map is given which shows the distribution of both species in the United States, based upon collections made during the course of the Investigation.

The treatment of Johne's disease, J. M'Fadyean, A. L. Sheather, and J. T. Edwards (Jour. Compar. Path. and Ther., 28 (1915), No. 3, pp. 196-216, figs. 9).—"In many cases of Johne's disease treatment with ferrous sulphate is followed by improvement, the diarrhea being checked and the loss of condition arrested. In the majority of such cases the improvement is not very great and the disease soon resumes its ordinary course. In some cases the treatment fails to effect even a temporary improvement or to check the diarrhea and loss of condition. In a minority of cases the treatment has surprisingly beneficial results, suggesting even a complete cure, with disappearance of the diarrhea and restoration of the animal from a state of emaciation to excellent condition. Even in the last class of cases a relapse which does not yield to a repetition

of the treatment is likely to occur, and it is doubtful whether the treatment ever effects an absolute cure. In view of its uncertainty and of the slow recovery of weight in the most favorable cases, treatment can not be advised except in special circumstances.

"As a rule the most economical plan is to destroy the subjects of Johne's disease as soon as the disease is manifested by distinct clinical symptoms. This course is indicated not only by the uncertainty and expense of treatment, but also because clinically diseased animals, even when under treatment, are highly dangerous unless strictly isolated.

"In the case of specially valuable animals, such as pregnant pedigree cows, treatment may justifiably be tried, in the hope that it may carry the animal over the period of parturition, even if it does not effect a cure. The treatment may also be justified in cases in which the disease has been diagnosed in apparently healthy animals by testing with avian tuberculin or 'Johnin,' and their slaughter is not considered expedient by the owner."

See also a previous note (E. S. R., 31, p. 283).

Studies on Texas fever. First communication, C. Sá and A. Cunha (Rev. Vet. e Zootech., 5 (1916), No. 6, pp. 288-363, pls. 4).—From studies on the methods of immunization it is concluded that late injections of trypanblue do not immunize against Texas fever without serious danger to the life of the animal. An early curative injection obviates this danger without in any way affecting the immunization of the animal. Early injections are therefore recommended.

A bibliography is included.

The occurrence of pleomorphism and mutation among members of the hemorrhagic septicemia group of organisms, J. P. M'Gowan and Chung Yik Wang (Jour. Path. and Bact., 20 (1915), No. 1, pp. 21-40, pls. 2).—The authors show "how an organism of the hemorrhagic septicemia group, by an increase of virulence through passage, has also concurrently been endowed with an increased biological activity on artificial media, whereby it grows much faster on these media and produces acid and gas fermentation in some carbohydrate media where it only produced acid or no change previously. It would seem to be essential for the success of this passage that the organism be taken directly from one animal to another without intervening growth on artificial media."

Vaccinations against hemorrhagic septicemia, J. B. Hardenbergh and F. Boerner, Jr. (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 1, pp. 55-59).—From experiments carried out on twelve herds of cattle and one of sheep the authors have concluded that "the use of 48-hour cultures of Bacillus bovisepticus subcutaneously in the dose of 0.5 cc. for sheep and 1 cc. for cattle is harmless. The immunity conferred by this vaccination has not been thoroughly demonstrated, but the sudden checking of losses in several herds may be evidence of some value. Incubation at 42.5° C. [108.5 F.] for 17 days failed to render the strains avirulent for rabbits in the dose of 0.2 cc."

A further contribution to the knowledge of the sheep disease, Septicæmia pluriformis ovium (hemorrhagic septicemia), and its control by serum vaccination, H. RAEBIGER, A. SPIEGL, and K. SCHERN (Deut. Tierärztl. Wehnschr., 23 (1915), No. 47, pp. 406-409, figs. 2; abs. in Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 1, pp. 112, 113).—A specific serum was obtained from three sheep which had been given repeated intravenous injections of virulent strains of Bacillus orisepticus. The serum was tested on white mice and found to protect them against a 1-cc. injection of a 24-hour bouillon culture of the bacilli.

The results of the use of the serum in 13 herds are submitted in tabular form and briefly discussed. The record of a case in a lamb, together with the autopsical findings, is also reported.

The use of the serum has given promising results, both in the recovery of diseased animals and in checking the spread of the disease among healthy animals.

Sheep scab, M. IMES (U. S. Dept. Agr., Farmers' Bul. 713 (1916), pp. 36, figs. 21).—This publication, which supersedes Farmers' Bulletin 159 previously noted (E. S. R., 15, p. 191), furnishes information for sheep raisers and livestock sanitary officers regarding the prevention, cure, and eradication of sheep scab.

A list of nematode parasites observed in the alimentary canal of sheep in England, C. L. Boulenger (*Parasitology*, 7 (1914), No. 3, pp. 240-249, pl. 1, figs. 4).—The author has found 13 species, distributed among 10 genera, to occur in England, or nearly half of the known species.

A note on the presence of Ostertagia trifurcata in the abomasum of a sheep in England, S. Cave (Parasitology, 7 (1914), No. 3, pp. 201-203, figs. 3).—In addition to numerous male and female specimens of O. circumcineta (Strongylus cervicornis), a strongyle identical with O. trifurcata was found in the fourth stomach of a ewe at the Cambridge University farm. It is stated that previous to this discovery the occurrence of this nematode had only been recorded from the United States.

[Hog-cholera studies] (North Dakota Sta. Rpt. 1915, pt. 1, pp. 5-8).—In the course of a general study of hog-cholera serum the influence of the time of bleeding upon the protective value of the serum was incidentally observed. Two weeks after immunization the hog was bled from the tail, and thereafter at intervals of one week until four bleedings were obtained. The detailed results of the work are presented in tabular form, but indicate in general a slight decrease in the potency of the serum.

Hog cholera and its prevention by the use of antihog-cholera serum, B. B. Flowe (Bul. N. C. Dept. Agr., 37 (1916), No. 3, pp. 32, figs. 19).—This bulletin considers the subject of hog cholera in general under the titles of cause, symptoms, sanitation, means by which the disease is spread, susceptibility, mortality, and antihog-cholera serum and its use in the treatment of the disease.

Stamping out hog cholera, J. W. Connaway (Columbia, Mo.: The Missouri Farmer [1916], pp. 80, figs. 29).—In addition to a general discussion of the manner of dealing with hog cholera by the author, several supplementary accounts are included, namely, Profitable Pork Production, by F. G. King (pp. 45-66) and Modern Systems of Swine Management, by L. A. Weaver (pp. 67-80).

Final report of the departmental committee appointed by the Board of Agriculture and Fisheries to inquire into swine fever, with minutes of evidence and appendix (Bd. Agr. and Fisheries [London], Final Rpt. Dept. Com. Swine Fever, pt. 4 (1915), pp. XVI+63; abs. in Jour. Compar. Path. and Ther., 28 (1915), No. 3, pp. 251-271).—This report includes the minutes of evidence and appendixes with experimental and statistical data. The committee submits the following conclusions:

"The manure of pigs suffering from swine fever is infective. A period of 14 days may be regarded as sufficient to bring about the disinfection of infective manure through natural causes. Rats are not, as has been suggested, pathological carriers of swine fever. All the available evidence suggests that swine fever is not disseminated by external parasites.

While persons, vehicles, and animals which have been in contact with the infected pigs or premises may carry infective material mechanically within the area of their movements, subject to the time limit indicated above, the evidence leads the committee to the conclusion that all wide dissemination of disease is due to the movement of infective pigs. A pig may become infective in three days after it has itself contracted infection and before it has actually exhibited clinical symptoms of the disease, and a pig which has contracted the

disease may continue to be infective for a variable period, the extent of which has not yet been fully ascertained, but which is often of considerable duration. There would appear to be cases in which healthy pigs which have not been visibly affected by swine fever, and which, on post-mortem examination, show no evidence of having suffered from swine fever, are infective and continue to be so for a considerable time."

In general it is concluded that "the continued prevalence of swine fever appears to be due principally to its highly contagious character and the difficulty of its recognition by the pig owner in its early stages and in its milder forms. To these causes must be added the difficulty of tracing the place of origin and the movement of pigs by which the disease has been spread. The extirpation of the disease is practicable only by such drastic measures of slaughter as would involve a prohibitive outlay, and by such severe restrictions on movement as would be fatal to the industry of pig keeping. Present circumstances, therefore, do not encourage the view that the extirpation of swine fever can be speedily accomplished or that such an objective should continue to be made the governing idea of administrative policy. This conclusion, however, does not exclude the possibility that new preventive methods may bring about a condition of affairs more favorable to the prospect of eradicating the disease, and the study of such methods is being actively pursued."

Recommendations for the control of the disease are also submitted. See also previous reports (E. S. R., 31, p. 884).

A plerocercoid found in the pig, RATZ (Abs. in Vet. Rec., 27 (1915), No. 1394, p. 498).—The name Sparganum raillietti is given to a yellowish-white filiform species which was found curled up on itself in the intermuscular connective tissue of a pig.

The occurrence and pathological importance of Strongyloides longus in swine, L. Reisinger (Wiener Tierürztl. Monatsschr., 2 (1915), No. 5, pp. 200-239, pl. 1, flg. 1).—This nematode (S. longus) occurs in swine in Austria, where, at times, it appears in extensive outbreaks, and it is also found in swine imported from Germany and England. It is the source of a disease in shoats characterized by anemia, emaciation, cutaneous eruption, diarrhea, and arrest of development. The mortality fluctuates according to the degree of infestation between 0 and 50 per cent.

Swine tuberculosis and the possibility of its practical control, O. Band and E. Holm (Ber. K. Vet. og Landbohöjskoles Lab. Landökonom. Forsög [Copenhagen], 88 (1915), pp. 5-63; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 7, pp. 959-961).—From the results of investigations to determine whether, under normal conditions, mammals can be infected by fowl tubercle bacilli and, conversely, fowls by the bacilli of the mammalian form of the disease, it is concluded that the bacillus of mammalian tuberculosis is the principal cause of the disease in swine, especially in the severest forms of the disease, which are, in the majority of cases, due to infection by cattle. About 90 per cent of the cases of local glandular tuberculosis are attributable to infection with the avian bacilli. Organic tuberculosis is due mostly to infection with the mammalian bacilli.

The results of a series of tests with tuberculin showed that a positive reaction to tuberculin practically always means that the animal is infected when it is a question of bovine tuberculosis, but the reaction gives no indication of the extent of the disease. These results were obtained with tuberculin prepared from the bacilli of mammalian tuberculosis. Avian tuberculin, as far as the disease caused by the bacilli of avian tuberculosis is concerned, possesses a diagnostic value which is at least equal, and sometimes even superior, to that of bovine tuberculin.

Sanitary measures with respect to the sheltering, feeding, etc., of the pigs are outlined. These measures, in actual trial, have been shown to reduce the prevalence of the disease markedly, and are therefore recommended.

The production of a hyperimmune serum for infectious abortion in mares, E. S. Good and W. V. Smith (Jour. Infect. Diseases, 18 (1916), No. 4, pp. 397-401).—Continuing the work on infectious abortion in mares at the Kentucky Experiment Station (E. S. R., 27, p. 580) the authors have demonstrated that a hyperimmune serum can be prepared which has marked bacteriolytic properties in vitro.

This serum protected rabbits from the lethal dose of the organism and lengthened the time for abortion in one guinea pig 12 days. It did not, however, protect a mare from an artificial infection. The infecting dose in this case, though, was much larger than would be possible in a natural infection.

It is indicated that the serum may prove of value in a stud where the infection is known to exist.

Nature, cause, and therapy of pernicious anemia of the horse, K. R. and R. Seyderhelm (Arch. Wiss. u. Prakt. Tierheilk., 41 (1914), No. 1-2, pp. 50-196).—Following a brief introduction and review of the literature, the authors deal with patho-anatomical and hematological investigations; the cause of the disease, including personal investigations (E. S. R., 33, p. 681); and therapeutic tests, including the removal of Gastrophilus larvæ and the use of curative serums; give a summary of the pathogenicity of Gastrophilus larvæ; etc. A bibliography of 46 titles is included.

Swamp fever (North Dakota Sta. Rpt. 1915, pt. 1, p. 5).—A brief statement of work carried on in continuation of that previously noted (E. S. R., 26, p. 287). Trials of the arsenico-mercuric treatment of swamp fever gave negative results, and this treatment is looked upon by the author as worthless in the American form of the disease.

In order to test the conclusions of the Seyderhelms (E. S. R., 33, p. 681) that swamp fever is due to a toxic agent associated with the larva of the botfly, ten botfly larvæ removed from a case of swamp fever were crushed in a physiological salt solution and injected intravenously into an experimental horse. In spite of a very severe reaction this animal did not succumb nor show any marked temperature reaction or anemia during the four months it was kept under observation. Its post-mortem appearances, however, resembled those of swamp fever. Blood drawn from this horse about two weeks before its destruction, as well as that drawn immediately before, proved to be virulent in experimental horses and, in all particulars, the clinical as well as the pathoanatomical aspects of these cases resembled those seen in the artificially induced swamp-fever cases. Blood drawn from the experimental horses infected by blood from the first-mentioned horse infected another horse in a similar manner. As an indication of the tenacity of the virus it is stated that the blood of an experimental animal infected in 1908 and to all appearances recovered produced the usual febrile reactions in a healthy experimental horse in 1915.

Notes on a little-known rabbit ear mite (Psoroptes cuniculi), A. B. Interest (Jour. Amer. Vet. Med. Assoc., 48 (1916), No. 6, pp. 726-730, figs. 3).—P. cuniculi, the cause of the disease commonly known as rabbit ear mange, is recorded from the United States for the first time. Its presence in the ears of two rabbits appears to have been responsible for their death. Listrophorus cibbus, found in the hair of a white rabbit kept in a pen adjacent to one of the rabbits mentioned above, is also recorded from America for the first time.

On the transmission from mother to offspring of immunity against fowl cholera, P. B. Hadley (Centbl. Bakt. [ctc.], 1. Abt., Orig., 76 (1915), No. 2-3,

pp. 196-206).—This material has been previously noted from another source (E. S. R., 31, p. 485).

On the anatomy of a fowl tapeworm, Amœbotænia sphenoides, F. J. Meggitt (*Parasitology*, 7 (1914), No. 3, pp. 262-277, pls. 2).—In addition to the anatomy the author briefly considers the life history of this parasite.

RURAL ENGINEERING.

A new irrigation weir, V. M. CONE (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 24, pp. 1127-1143, figs. 16).—Experiments conducted under a cooperative agreement between the Office of Experiment Stations and the Colorado Experiment Station are reported. The purpose was to develop a weir "that would be self-cleaning, require a minimum amount of labor and material for construction, measure discharges with an accuracy commensurate with field conditions and irrigation demands, and be easily operated by the ordinary man,"

Altogether 277 experiments were made with a new type of weir using both rectangular and 90°-triangular notches. Thirty-four different arrangements of weir box were used for the rectangular notches, the length of weir crest varying from 1 to 4 ft., and the width of weir box at both the crest and 20 ft. from 1.5 to 6 times the length of crest. Floor lengths of 32.67 and 20 ft. were used. From the results a weir was developed, the general formula for the discharge of which is Q=(3.83-0.7L) Lh (1.52+0.01L) in which Q=the discharge, L=the length of crest, and h=the head on the weir. The computed discharges for the new weirs are given in tabular form.

The tests brought out the following advantages: "The new irrigation weir is self-cleaning.... No lowering of the canal grade or building up of the banks is required for the construction of the weir box. The weir box has only one-fourth the depth and a less width than is required for a full-contraction weir. Less excavation and less materials are needed in the construction, and the cost of the weir is therefore greatly decreased. It may be installed by the farmer without expert assistance and with the tools ordinarily at hand. Its operation does not require special training. Its accuracy is consistent with practical demands and will remain constant. It can not be easily tampered with or accidentally injured so as to alter its discharge. There are no working parts which require attention for proper operation. There is practically no upkeep expense if the weir is well constructed of durable materials. When the discharge tables are used, no computations are required."

Specifications for the construction and use of the new weir are as follows: "The weir notch is rectangular in form, with sharp crest and sides. The floor of the weir box must be level with the crest.... The grade of the canal downstream from the weir must be low enough to give free fall and complete aeration to the nappe. The floor of the weir box must be level throughout, and there must be no sudden or decided differences in elevation between the floor and the grade of the channel of approach. The weir box must be placed in the center of the ditch, so the axial line of the box corresponds with the axial line of the canal, in order that the water may enter the weir box in straight lines. The width of the weir box must be twice the length of the weir crest at the plane of the weir, and two and a half times the length of the weir crest at a distance of 20 ft. upstream from the plane of the weir....

"It is necessary that a still box be placed outside the weir box and connected through the side of the weir box with one or more 1-in, pipes located 6 ft, from the plane of the weir. The pipe should be placed near the floor

of the weir box to insure its being submerged for low heads, and care must be used to place the pipe normal to the side of the weir box, and not normal to the axis of the box.... The still box should have inside dimensions of at least 1 ft. by 1.5 or 2 ft., with such depth as is necessary....

"The new irrigation weir may be constructed of lumber, but the design is such that it may be easily constructed of concrete. There would be no difficult form work required for the concrete, and it would make an inexpensive, durable, and satisfactory measuring device, especially if the angle-iron sides and crest of notch were used in connection with the concrete box."

Fourth biennial report of the Department of Engineering of the State of California, 1912–1914 (Bien. Rpt. Dept. Engin. Cal., 4 (1912–1914), pp. 285. pls. 47).—This report reviews the history of engineering work in California and deals with the practice in the State on the special subjects of architecture, hydroeconomics, and state roads and highways. Data on water and water-power resources in the State, obtained in cooperation with the U. S. Geological Survey, and data from irrigation investigations, conducted in cooperation with the Office of Experiment Stations of this Department and with the California Experiment Station, are also reported. These include a progress report of irrigation investigations by F. Adams for 1912 to 1914 (E. S. R., 29, p. 588), a report of an investigation of wells in the Imperial Valley by C. E. Tait, and a report on investigation of wells in the Imperial Valley by W. A. Hutchins.

Report on irrigation for the year 1914 (Dept. Int. Canada Ann. Rpt. 1914, pt. 7, pp. 222, pls. 25, figs. 33).—Reports are included on the Cypress Hills, western Maple Creek, and Calgary irrigation districts; on the south Saskatchewan water supply and Oldman River diversion projects; on the Cypress Hills reservoir surveys; on cost data on reservoir water; on work in connection with the international waterways treaty; on duty of water investigations; and on principles governing the design and operation of irrigation systems.

Duty of water experiments and farm demonstration work (Dept. Int. Canada, Irrig. Ser. Bul. 4 (1915), pp. 62, pls. 9, figs. 15).—This report presents detailed information dealing particularly with practical field irrigation work and general returns on irrigation crop production. Sectional reports are included on the duty of water at Strathmore and Ronalane, Alberta, alkaline soil conditions, and a general crop report by G. D. Walters; the duty of water at Coaldale, Alberta, by W. H. Snelson, and crop report for the Eastern Maple Creek District, by M. H. French, the Western Maple Creek District, by H. R. Carscallen, and the Calgary District, by R. H. Goodchild.

Report on the climatic and soil conditions in the Canadian Pacific Railway Company's irrigation project, western section (near Calgary, Alberta) (Dept. Int. Canada, Irrig. Scr. Bul. 3 (1915), pp. 24).—This report includes sections on climatic conditions and on the temperature of water in irrigation canals, by G. N. Houston, and on soils and analysis of water from irrigation canals, by F. T. Shutt.

In the first section it is concluded that "the climatic conditions in the western section are similar to those in several other places where irrigation has been successfully practiced for many years and, therefore, there is no reason, so far as climate is concerned, why it should not be successful there. . . . It is evident that irrigation is very desirable on the western section."

With reference to temperature of water it is concluded that "the water applied to crops on the western section is of a higher temperature than that used in many places where irrigation is carried on successfully, [and] is generally of a higher temperature than the rain water. The application of irrigation water to the crops in the western section will not result in seriously retarding their growth."

Geology and water resources of Sulphur Spring Valley, Arizona, O. E. Meinzer and F. C. Kelton (Arizona Sta. Bul. 72 (1913), pp. 231, pls. 15, figs. 32).—This is a reprint of U. S. Geoolgical Survey Water-Supply Paper 320 (E. S. R., 30, pp. 18, 85). The publication previously noted as Bulletin 72 of the Arizona Station (E. S. R., 32, p. 513) constitutes one chapter of the present publication.

The Ohio water problem, C. E. Sherman (Ohio State Univ. Bul. 20 (1915), No. 10, pp. 135, pls. 6, figs. 19).—"This bulletin is directly the result of two lectures, one given in the engineering and one in the university lecture course at Ohio State University in January, 1913, and January, 1914, respectively. The subject of the first was river and harbor improvements, and of the second the Ohio water problem." The following chapters are included: Preliminary considerations, floods, flood-protection plans, economics of water transportation, broader aspects of water transportation, water power, miscellaneous uses, Sandusky-Scioto conservancy, and a state-wide survey. Maps and tabular and graphic data are included.

Flood protection in Indiana, W. K. Hatt (*Proc. Ind. Acad. Sci., 1914, pp. 149-156*).—This is a brief review of the findings of the Indiana Flood Commission, appointed to study flood causes and flood-prevention methods in Indiana.

Report from the water laboratory, H. E. Barnard (Ind. Bd. Health, Ann. Rpt. Chem. Div. Lab. Hyg., 9 (1914), pp. 155-163, figs. 5).—Of the 1,645 samples of water analyzed during 1914, 702 were collected from so-called shallow wells, 656 from deep wells, 96 from streams, 84 from springs, 48 from cisterns, 27 from lakes and ponds, and 32 from miscellaneous sources; 1,342 of these samples were from private supplies, mainly private wells, while 303 samples were from public supplies.

Of the total number examined, 1,021 waters were reported as good, 414 as bad, and 210 as doubtful. Of the private water supplies examined, 509 were from deep wells, 684 from shallow wells, 48 from cisterns, and 69 from springs; 767 of all the private samples examined were potable, 381 were condemned as bad, and 194 were classed as doubtful. Of the 509 deep wells analyzed, 426 were furnishing good water, 36 were reported as bad, and 47 as doubtful. Of the 684 shallow wells, but 246 furnished potable water, while 308 were unqualifiedly bad, and 130 were doubtful. Of the 48 cistern waters, 22 were good, 21 bad, and 5 doubtful. Of the 69 spring waters, 49 were good, 10 bad, and 10 doubtful. These results are taken to indicate that the shallow well as a source of private water supply is greatly to be feared.

Limits of potability of the waters of the Province of Buenos Aires, F. A. Mazza (An. Soc. Quim. Argentina, 3 (1915), No. 10, pp. 167-183).—Data on the maximum tolerable chemical limits of potability of the waters of different parts of the Province of Buenos Aires, as determined by local surroundings and conditions, as well as by analyses, are reported.

Sewage treatment and disposal, B. J. Ashley (Farm Implements, 30 (1916), No. 1, pp. 70, 72).—In a brief statement of the fundamental principles of the design of small sewage treatment and disposal systems, special attention is drawn to the importance of the colloidal media for aerobic organisms in nitrification systems and to the existence and action of colloids in sewage as important factors affecting design.

Activated sludge method in England (Municipal Jour., 40 (1916), No. 6, pp. 199, 200).—Recent experiments at Salford, England, on duration of aeration, winter operation, and possibility of continuous flow led to the conclusion "that it would be perfectly practicable to reduce the aeration to one hour." It is also thought that "where only domestic sewage is treated the time of aeration

might be reduced still lower.... As to the effect of cold weather, the experiments on two-hour and one-and-a-half-hour aeration covered the coldest part of the year, and during this time the lowest recorded temperature of crude sewage treated was 51° F.... The best results obtained were when working with from 20 to 25 per cent of sludge, the excess being usually pumped to the drying area from the first and second settling tanks twice a week. From the comparatively small effect of the sterilizing trade wastes it is concluded that 'the influence of sterilizing substances which play such havoc with bacteria beds generally can readily be overcome.'"

A new method of land clearing, H. D. Scudder (*Oreg. Countryman*, 8 (1916), No. 4, pp. 259-266. figs. 7).—Experiments with a newly developed stump burning method are reported.

The outfit required consists of two heavy cast-iron pieces, namely, the furnace and the hood. The furnace is so placed against the unbanked portion of the stump as to direct the fire toward its center the long way through and is then banked. A stovepipe is placed in the top of the furnace and a draft pipe from 10 to 12 ft. long into the front. A blast of flame is thereby driven against the heart of the stump, and, after burning through, the furnace is removed and the hood, fitted with the chimney, put in its place and charpitting continued until the stump is destroyed.

The tests so far show that the time the stump burner outfit is required averages about one day for each foot diameter of stump. The tests indicate that the cost will vary from 50 to 80 cts. per stump if all the labor is hired.

Proceedings of the eleventh annual convention of the American Road Builders' Association, 1914 (*Proc. Amer. Road Builders' Assoc.*, 11 (1914), pp. 391, pl. 1, figs. 10).—These proceedings include the following special papers:

Road and Pavement Dimensions—Widths, Depths, and Crown, by L. White; Road Foundations—Concrete, Telford, Gravel, etc., by J. A. Johnston; Organization of a State Highway Department, by J. N. Carlisle; Traffic—Present Tendencies, Probable Development, and Regulation, by A. W. Dean; Machinery for Construction and Maintenance—State, Municipal, Contractors, Traction Haulage of Stone, Care of Machinery—Instructions to Engineer and Operator, by T. R. Agg; Brick Roads and Streets, by J. Laylin; Surfaces or Floors for Bridges, by C. Older; Bituminous Construction and Maintenance—Recent Practice, by W. D. Uhler; Concrete Roads, by H. J. Kuelling; Recent Practice in Construction in Wood and Granite Block, by W. A. Howell; Present Practice in Earth and Gravel Road Construction and Maintenance, by I. O. Baker; Street Paving in Small Cities, by T. H. MacDonald; Convict Labor in Road Construction, by T. J. Ehrhart; and Dust Prevention and Street Cleaning, by W. H. Connell.

Relation of mineral composition and rock structure to the physical properties of road materials, E. C. E. Lord (U. S. Dept. Agr. Bul. 348 (1916), pp. 26, pls. 8, figs. 3).—In this bulletin a microscopic method of rock analysis by means of a cross-line grating is reviewed and the average mineral composition and physical properties of all rocks analyzed and tested in the Office of Public Roads and Rural Engineering up to January 1, 1914, are given in tabular form. "This material has been classified according to composition and structure and the rock-forming constituents have been discussed under the groups of primary and secondary minerals with a view to explaining their essential physical characteristics. The physical properties of rocks for road making and the method of testing this material have also been given and the results obtained used to show, first, in a general way, the relation between these properties and the mineral composition and structure of rocks; and, secondly, to point out more specifically the effects of secondary compounds upon them."

The results obtained in these investigations are taken to indicate the following:

"Igneous and nonfoliated metamorphic rocks, owing to a preponderance of hard silicate minerals combined with greater uniformity in structure, are more durable than other road-making materials, finer-grained varieties offering greater resistance to abrasion than coarse-grained types. The resistance to wear of igneous and metamorphic rocks, containing an abundance of quartz, hornblende, augite, epidote, and garnet, is greater than that of similar rocks rich in mica, chlorite, serpentine, and calcite.

"Foliated metamorphic rocks, owing to the parallel arrangement of their mineral constituents, are, as a rule, deficient in toughness, and therefore not well adapted to road construction. Sedimentary rocks are usually deficient in wearing properties, except in the case of highly indurated sandstones, containing a moderate amount of siliceous clay, cement, and limestones or dolomites rich in quartz and having very little clay.

"Rocks for road making break down under impact into fragments, the shape and physical character of which are conditioned by mineral composition and structure.

"The effect of weathering is generally to lower the resistance to wear of road materials, owing to the development of soft, in part colloidal, products of alteration. Where the secondary minerals are harder and more crystalline the wearing properties of the rocks are proportionately increased.

"The cementing value of road materials is conditioned chiefly by the colloidal products of rock decay and increases in a general way proportionately with these products, reaching a maximum in rocks free from quartz. The slaking property of rock powders is dependent in the case of siliceous igneous and metamorphic rocks chiefly on the physical character of the primary mineral components, whereas in basic igneous rocks and sandstones it is caused to a large degree by colloidal products of rock decomposition."

See also a previous note by the author (E. S. R., 25, p. 890).

A new penetration needle for use in testing bituminous materials, C. S. Reeve and F. P. Pritchard (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 24, pp. 1121-1126, pl. 1).—Experiments conducted in the Office of Public Roads and Rural Engineering are reported, as a result of which the following conclusions are offered:

"The No. 2 sewing needle which has heretofore been used for the penetration test can not be taken indiscriminately, but must be carefully selected and standardized. There is no recognized established standard with which new needles can be compared, and it is not feasible to accurately describe the dimensions of a parabola needle. The so-called standard needles furnished with penetration machines may vary among themselves.

"The writers have designed a needle which gives results in close accord with existing standards and has, moreover, the advantage of being accurately described and easily reproduced. The needle is made by placing a 2-in, length of 0.041-in, annealed-steel drill rod in the chuck of a high-speed lathe and by means of a fine sharp file turning the end to a sharp point having a 4-in, taper. When it has been made as smooth and sharp as possible by this means the needle is tempered, then ground to a sharp point with a good stone, after which it is smoothed and polished with emery dust, crocus cloth, and rouge, and finally held carefully on a buffing wheel. The finished needle should be sufficiently smooth and sharp to enter and pass through a piece of ordinary writing paper without sticking or friction. This new needle must have as sharp a point and smooth a surface as any sewing needle. The important thing is to have the taper straight,

beginning \(\frac{1}{4} \) in. from the end, and the needle above the taper exactly 0.04 in. in diameter."

The use of hydrated lime in Oregon State concrete roads, R. S. Edwards (Nat. Lime Manfrs. Assoc. Bul. 18 (1915), pp. 15, figs. 2).—A review of concrete road practice in Oregon in 1914, especially in Jackson County, is given, which, it is thought, has proved that the addition of hydrated lime in quantities ranging from 5 to 10 per cent of the weight of the cement used in concrete paving work shows the following advantages:

"(1) Decrease in labor cost in placing and surfacing the concrete.... (2) Twenty per cent reduction of the transverse cracking of a 6-in. concrete road slab under Jackson County climatic conditions, resulting in a saving of $\frac{1}{2}$ ct. per square yard, where asphalted felt joints were used, or 2 cts. per square yard, where armored joints were used. There is also a future saving in maintenance cost.... (3) The concrete surface of a pavement in which hydrated lime was used has actually shown a more uniform and dense finish and a more uniform wear."

In conclusion, the following suggestions are made: "In one-course concrete pavements, which are not to be treated or surfaced with bitumen or oil, 8 per cent of hydrated lime would seem sufficient to secure the stated results. In concrete pavements which are to be treated with a bitumen wearing surface, from 10 to 12 per cent of hydrated lime should prove sufficient and beneficial, and in such cases an increase in the aggregate is justified. In two-course concrete pavement, the wearing surface of which is to take the traffic, it would seem advisable to use 10 per cent hydrated lime in the base course with 5 per cent in the top course. In rich surface mixtures, such as one cement, one sand, and two crushed-rock screenings, the amount of cement per yard of concrete is high, and a greater percentage of hydrated lime than 5 per cent is not necessary and should not be used."

See also a previous report by the author (E. S. R., 31, p. 387).

Loading of bridge floors (Cement Era, 14 (1916), No. 2, p. 60).—Tests by the Ohio Highway Department on the distribution of concentrated loads on highway-bridge floors are reported, the object of which was "to obtain a sufficient knowledge of the distribution of loads through and by concrete floor slabs to enable the designer to rationally proportion the joists of a slab floor, and also the slab itself, to carry concentrated loads. . . .

"The following conclusions regarding the distribution of concentrated loads on a reinforced concrete slab, to the floor joists, seem to be warranted by these tests: (1) The percentage of reinforcement has little or no effect upon the load distribution to the joists, so long as safe loads on the slab are not exceeded. (2) The amount of load distributed by the slab to other joists than the one immediately under the load increases the thickness of the slab. (3) The outside joists should be designed for the same total live load as the intermediate joists. (4) The axle load of a truck may be considered as distributed uniformly over 12 ft, in width of roadway. (5) If the slab has ample grip on the upper Aurge of the I-beam and is continuous over the floor beams and the joists are riveted to the web of the floor beams, the live load stress in the joist may be but one-half as great as for a similar load on the bare I-beam supported at its ends. (6) Under these favorable conditions the axle load in a panel of not than 20 ft, may be assumed as uniformly distributed over two-thirds of the length of the joists considered as simple I-beams supported at the ends. Without these conditions, the load may be assumed as uniformly distributed over a length of at least 5 ft.

"In a slab of a certain span and indefinite width, there is some width symmetrical with the load beyond which a single concentrated load will have no

effect. The stresses in this slab will be a maximum under the load and will decrease in each direction from it. The 'effective width' of a slab is that width used in designing over which a single concentrated load may be considered as uniformly distributed on a line down the middle of the slab parallel to the supports.

"The tests of slabs seem to warrant the following conclusions: (1) The 'effective width' is affected very little by the percentage of transverse reinforcement (parallel to supports). (2) The 'effective width' decreases somewhat as the load increases. (3) The 'effective width' in percentage of the span decreases as the span increases. (4) The following formula will give a safe value of 'effective width' where the total width of slab is greater than $1\frac{1}{3}$ 8+4 ft.: e=0.6 8+1.7 ft., where e=effective width in feet and S=the span in feet."

Charts for estimating the strength of bolts, W. F. FISHER (Power, 43 (1916), No. 2, pp. 42, 43, figs. 2).—Two charts are presented, showing the strength of threaded bolts from 0.25 to 2.5 in. in diameter. These were prepared from the formula $L=A\times f$, in which L=the load on the bolt in pounds in tension, A=the area in square inches of the bolt at the root of the thread, and f=the unit fiber stress on the bolt material at the root of the thread in pounds per square inch.

Explosion period in gas engine, R. S. King (*Power*, 43 (1916), No. 2, pp. 48, 49, fig. 1).—The results of experiments on a 6-horsepower, 4-stroke-cycle, hit-and-miss governed gas engine with make-and-break ignition are reported, which indicate that the rapidity of explosion is greatest with the best mixtures and increases with the compression.

Gasoline farm tractors, P. S. Rose (Engin. Mag., 49 (1915), No. 5, pp. 750-752, figs. 6).—This is a review of the development during the past few years of internal combustion machines for heavy haulage about the farm.

Demonstrations of motor plows and tractors (Jour. Bd. Agr. [London], 22 (1915), No. 8, pp. 760-766).—A brief description of different motor plowing outfits and a review of results obtained in demonstrations at different localities in England are given.

Demonstration of mechanical cultivation and of agricultural motors, Parma, 1913, M. Castelli and G. D. Mayer (Concorsi di Aratura Meccanica e di Motori Agricoli. Milan: Cattedra Ambulante d'Agricoltura di Parma, 1913, pp. 234, figs. 57).—The first part of this report describes and illustrates a number of mechanical cultivating outfits of both American and European make, including internal-combustion motor plows and cultivators, internal-combustion and steam tractors, and cable plowing outfits, and presents and discusses the results of tests of each on a soil of widely varying texture. The second part describes and illustrates a number of stationary and portable internal combustion farm engines, mainly of European make, and reports and discusses tests of each. In both sets of tests internal-combustion motors were included, operating on high- and low-grade fuels.

The mechanical cultivation of the soil, P. Mathis (Agr. Colon. [Italy], 9 (1915), Nos. 3, pp. 129-147; 4-5, pp. 227-249, figs. 5; 6, pp. 345-358, figs. 8; 7, pp. 403-419, figs. 5).—This article points out the importance of mechanical cultivation in the agriculture of colonial Italy, describes steam, electrical, and internal-combustion power in their application to mechanical cultivation, and describes and discusses a large number of mechanical plowing outfits, including tractors, motor plows, and cable outfits of both American and foreign make.

The relation of mechanical cultivation to intensive agriculture, A. DAUTRY (In Primera Semana Social Agricola. Santiago de Chile: Universidad Católica

de Santiago, 1914, pp. 15-52, figs. 12).—This article points out the importance of good physical and chemical condition of soil to crop production and describes and illustrates a number of mechanical tillage outfits which are adapted to intensive agriculture. A bibliography is appended.

A new spray nozzle, C. W. Woodworth (U. S. Dept. Agr., Jour. Agr. Research, 5 (1916), No. 25, pp. 1177-1182, pls. 2, fig. 1.)—A new principle in nozzle construction is described as developed at the California Experiment Station whereby a flat spray can be produced with a uniform distribution of the water comparable to that of the hollow cone of spray from a cyclone nozzle. "The principle finally discovered was that when two streams meet across half their section the resulting sheet of spray will be of practically uniform thickness throughout, occupying a plane 45° from the plane of the streams and finally breaking up into drops of great fineness and uniformity. . . A flat spray is more easily directed and produces a more uniform distribution than the cone of spray from a cyclone nozzle. Uniformly fine drops of spray aid in securing uniformity of distribution. The new nozzle allows some variation in size of spray. It also may be made into a long or short distance nozzle. It can be easily constructed by modifying existing nozzles and may be adjusted if it becomes worn."

Wire fencing, W. Somerville (Jour. Bd. Agr. [London], 22 (1915), No. 8, pp. 7:21-7:37, fig. 1).—A brief description of the methods and tools used in the construction of wire fences inclosing stock pastures in England and Scotland is given, together with statements of cost.

Rural structures of wicker, Camille Arnould (Vie Agr. et Rurale, 5 (1915), No. 16, pp. 292-294, figs. 6).—The uses of wicker in the construction of fences, shelters, buildings for stock, cottages, etc., and for river-bank protection against erosion are described.

RURAL ECONOMICS.

Selected readings in rural economics, compiled by T. N. CARVER (Boston and London: Ginn & Co., 1916, pp. VIII+974, figs. 11).—This book contains a large number of selected articles, chosen with a view to making available to the student of agricultural economics a mass of material which has been published in widely different places and treating of the general principles of rural economics, the agricultural history of Europe and America, land tenure, agricultural labor, the farmer's business, agrarian movements in the United States, rural organization and marketing, and agricultural policy.

The articles included are as follows: The Influence of the Crops upon Business in America, by A. P. Andrew; The Influence of Farm Machinery on Production and Labor, by H. W. Quaintance; Crop Yields and Prices, and Our Future Food Supply, Some Suggestions for City Persons who Desire to Farm, and Some Important Factors for Success in General Farming and in Dairy Farming, by G. F. Warren; Iowa and Bavaria Crop Yields per Acre and per Man, by E. A. Goldenweiser; Agriculture in the Middle Ages, by W. F. Allen; Inclosures in England in the Sixteenth Century, by E. F. Gay; Yeoman Farming in Oxfordshire from the Sixteenth Century to the Nineteenth, by H. L. Gray; The Decline of Landowning Farmers in England, by H. C. Taylor; The Epochs of German Agrarian History and Agrarian Policy, by C. J. Fuchs; The Disposition of Our Public Lands, by A. B. Hart; Southern Agriculture, 1790-1860, by M. B. Hammond; The Agricultural Development of the West During the Civil War, by E. D. Fite; Agricultural Development in the United States, 1900-1910, by J. L. Coulter; The Movement of Wheat Growing-A Study of a Leading State, Relation of Jobbers and Commission Men to the Handling of Produce, and Studies in Egg Marketing, by C. W. Thompson; The Law and Custom of Primogeniture, by G. C. Brodrick; The Land System of France, by T. E. C. Leslie; The Land System of Belgium and Holland, by E. de Laveleye; The State Small Holdings in Denmark, The English Agricultural Laborer, by H. R. Haggard; Tenancy in the United States, by G. K. Holmes; Tenancy in the North Atlantic States, Tenancy in the North Central States, Tenancy in the Southern States, and Tenancy in the Western States, by B. H. Hibbard; On the Recollections of a Hired Man, by M. A. Barber; The Farmer's Income, by W. J. Spillman; Profits that Farmers Receive, by E. H. Thomson; The Rise of the Granger Movement, and The Outcome of the Granger Movement, by C. W. Pierson; The Populist Movement, by F. L. McVey; An Analysis of Agricultural Discontent in the United States, by C. F. Emerick; Agricultural Syndicates in France, by H. W. Wolff; The Technique of Mediæval and Modern Produce Markets, by A. P. Usher; Studies in the Marketing of Farm Products in France and England, by E. K. Carver and G. L. Wilson; The Irish Land Purchase Act of 1903, by C. F. Bastable; State Bounties and the Beet-sugar Industry, by P. T. Cherington; Beet Sugar, by F. W. Taussig; and Agricultural Credit in the United States, by J. E. Pope.

Land tenure reform and democracy, G. E. PUTNAM (*Polit. Sci. Quart.*, 31 (1916), No. 1, pp. 53-65).—Among the solutions of our land tenure problem suggested by the author are the acquiring of the land by the Government to be leased in such a way as to render ultimate ownership possible, the imposing of an additional tax on land not operated by owners and a progressive tax upon all holdings above a certain minimum value, and the establishment of better systems of land credit. He claims that the present system places a premium upon tenancy because of the short term of mortgages and the interest charges being high compared with the natural returns of the land.

The State as farmer, G. Radford (London: Smith, Elder and Co., 1915, pp. 149).—The author outlines his conception of the relation of the State to farming. He believes it is the function of the State through proper instruction and regulation to bring about such use of land as to prevent waste, as for example the more extensive production of poultry and pork to consume the waste products of the farm, the keeping of a type of cow giving a high yield of butter, the destruction of weeds, better marketing facilities, and arrangements to prevent gluts.

Relation of the Government to the marketing problem, B. T. Galloway (Cornell Countryman, 13 (1916), No. 5, pp. 370–372, 398, 400, 402).—Among the ways suggested that the Government may function in solving the marketing problem are in lending its aid in determining and fixing standards, in developing the principles that should govern in the storing and warehousing of farm products, in extending knowledge concerning the marketing of farm products, and in gathering and disseminating information regarding the supply and demand for perishable products that would be helpful to the producer and consumer alike. The author believes that there should be a combined climate, crop, and market information service somewhat similar to the present system of reporting crop and weather conditions.

Community organization for live stock improvement, G. C. Humphrey (Hoard's Dairyman, 51 (1916), No. 4, pp. 137, 152, 153, fig. 1).—The author has given a brief history of the community live-stock organization movement in Wisconsin and outlines some of the essentials to success. He points out the advantages of community organization as follows: In dairy cattle associations it encourages cow testing work; it provides a most economical system of advertising and offers special inducement for buyers seeking carload lots of ani-

mals; it offers better opportunities for men to cooperate in buying and importing foundation stock; and it gives the farmer new ideas toward which to work and makes farm work more fascinating and enjoyable.

Rural clubs for women, EMMA R. DAVISSON (Nebr. Col. Agr. Ext. Bul. 36 (1915), pp. 3-14, figs. 3).—This bulletin gives a number of typical examples of women's rural clubs, directions for organizing and conducting clubs, a model constitution, and methods of procedure. It also contains a brief outline for a course of study for home economics clubs and topics for club discussions.

Farm mortgage credit in New Hampshire, G. C. Smith (N. H. Col., Arts and Sci. Research Bul. 2 (1916), pp. 16, figs. 3).—This study is based upon answers to a questionnaire sent to banks and farmers in New Hampshire.

The savings banks and building and loan associations all reported that the rate at which loans are made on farm mortgages is 5 per cent. Of the farmers reporting on loans from banks 88 per cent reported the rate as 5 per cent and the remaining 12 per cent as 6 per cent; of the farmers reporting on loans from other sources 76 per cent reported the rate as 5 per cent, and the remainder as 6 per cent. With reference to the payment of mortgages, 75 per cent of the farmers reported them as payable on demand, and 73 per cent stated that this system was satisfactory. The reports indicated that the average loans approximated 58 per cent of the total value of the property mortgaged. The banks reported that 84 per cent of the mortgage loans was taken care of by the banks, while the farmers reported that 61 per cent was so obtained.

The author believes that well-planned rural-credit institutions are imperative in some of our States and would undoubtedly serve a useful purpose in New Hampshire, particularly in those sections of the State where the farmers have experienced difficulty in securing loans from the savings banks. The survey, however, does not indicate, in his opinion, that existing conditions in New Hampshire are so distressing as to require extensive loaning facilities of a kind different from those already in existence,

An agricultural survey of Brooke County, O. M. Johnson and A. J. Dadisman (West Virginia Sta. Bul. 153 (1915), pp. 32, figs. 18).—The authors summarize the results of this survey, compiled from the records of 201 farms with an average labor income of \$125, as follows:

"In order to secure an income that will permit a satisfactory standard of living, the farm business must be of considerable size. Where the situation permits very intensive farming, such as trucking, fruit growing, etc., a large business may be conducted on a few acres; but where the conditions are such as to require general farming, as most kinds of live-stock farming, the acreage must be larger. A farmer with a very small acreage who can not engage in intensive farming because of a lack of markets for the products would find it to his advantage to rent additional land, or, in some cases, to sell his small farm and invest his capital in the necessary work stock and implements to farm a larger area and become a tenant on a farm of sufficient size to give an opportunity to earn a good income.

"There is a close relation between the amount of capital invested and the family income, but on many farms where the capital is large, organization is poor, and there is no income for labor. . . . A combination of enterprise including dairy, truck, fruit, or general crop farming organized to suit individual needs seems to be most desirable. . . .

"There is no striking difference in production in the groups of farms of different sizes nor in the small and large herds. The form in which the product is marketed has a considerable influence on the value of the product per cow—market milk paying best....

"The labor income on farms operated by tenants is larger than on farms operated by owners, but the tenant's capital is small and his income available for use of the family is smaller than that of the owner operating his own farm. Share renting usually gives the owner a larger return on his investment than cash rental.

"A farm which gives a labor income of \$500 in addition to furnishing a home and a large part of the living is a good business. While the number making this labor income is not large, about 20 per cent, indications are that opportunities are open for farmers on well-organized farms in this county.

"Since truck and dairy farming are the most profitable types and a rather large area is available which is adapted to these industries, they can be materially increased. Markets for the products will be the first limitation. So far as can be seen now there is little danger of oversupplying the markets that can be reached. The farms some distance from the railroads or trolley lines can produce butter at a profit if good producing cows are kept, and in addition many of these farmers would find it profitable to develop gradually pure-bred herds from which they might sell surplus stock."

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt. 2 (1916), No. 3, pp. 21–28, fig. 1).—Included in this report are estimates concerning the amount of wheat, oats, corn, and barley on farms March 1, the amounts shipped out of counties where grown, and the amount of the crop of merchantable quality. Data are also given showing the wheat held at country mills and elevators, wheat exports, prices, and freight rates, the amount of the merchantable corn crop, the farm movement and prices of wheat by months, and a diagram showing the receipts of wheat weekly at primary markets for 1914–15 and 1915–16, as compared with the five-year average for 1910–1915.

The wages of male farm labor with and without board are given per month, per day at harvest season, and per day at other than harvest season. The estimated farm value of important products on February 15 and March 1 is given, together with the range of prices of agricultural products at important markets. Data are given showing the percentages for the different grades of the total cars of winter and spring wheat inspected at Chicago for a series of years. The conditions of crops in Florida and California and of the early southern truck crops on February 1 and March 1 are given.

The Louisiana cane sugar crop for 1915 is estimated at 136,500 short tons as compared with 242,700 short tons in 1914. The Texas onion crop of 1916 is estimated to cover 10,657 acres as compared with 9,343 acres in 1915. Other miscellaneous data are included.

Agricultural statistics of Argentina, 1913-14 (Estad. Agr. [Argentina], 1913-14, pp. 186).—This report continues information previously noted (E. S. R., 31, p. 595), adding data for later years.

Agriculture of Morocco, J. Chailley (Compt. Rend. Acad. Agr. France, 2 (1916), No. 2, pp. 48-60).—These pages give the extent of the production of the principal agricultural crops and the number of live stock, and describe the general agricultural conditions.

Estimates of area and yield of principal crops in India, 1914–15 (*Dept. Statis, India, Est. Area and Yield Princ, Crops India, 1914–15, pp. 25, pls. 3*).—This report contains statistical data concerning the area and production of the principal crops for the crop seasons 1905–6 to 1914–15 by Provinces. Methods of determining the estimates and collecting the data are outlined.

AGRICULTURAL EDUCATION.

The forthcoming situation in agricultural work-II, L. H. BAILEY (Science, n. ser., 43 (1916), No. 1099, pp. 77-87).—This address of the retiring vicepresident of Section M of the American Association for the Advancement of Science is in continuation of an address at the previous annual meeting (E. S. R., 32, p. 102), and has been noted elsewhere (E. S. R., 34, p. 396).

On the training of teachers of nature-study, R. E. WAGER (Nature-Study Rev., 12 (1916), No. 2, pp. 47-55).—The author discusses the training of teachers of nature study as it concerns the understanding of the nature of the physical and mental development of the child and the elements in training essential to wise and forceful instruction.

High school extension in agriculture, C. H. LANE (Better Schools, 2 (1916), No. 2, pp. 44-48).—The author calls attention to the need of lengthening the school year and of securing a larger daily attendance of pupils, and discusses the problem of making the school funds and equipment of rural high schools contribute to the education of all the people of the school district by means of extension work in agriculture. Extension work is defined and suggestions are given concerning different forms of such work and the training of high school agricultural extension workers.

[Progress in agricultural education in Manitoba] (Rpt. Dept. Agr. and Immigr. [Manitoba], 1914, pp. 23-29, 90-93, pl. 1, figs. 4).-This report contains information for 1914 similar to that given for 1913 (E. S. R., 33, p. 396).

Annual report of the director of education [of the Philippines] (Ann. Rpt. Dir. Ed. P. I., 15 (1914), pp. 166, pls. 12).—This report includes an account of progress in agricultural and home economics instruction in the Philippine Islands from January 1 to December 31, 1914.

Teachers' farm school (Jour. Dept. Agr. Victoria, 13 (1915), No. 11, pp. 641-660, figs. 13).—This is a report on the first teachers' farm school in Victoria, Australia, held September 20-24, 1915, at the State Research Farm, Werribee, by the state departments of agriculture and education. Lectures and practical field demonstrations were held daily from 9 a. m. to 10 p. m., attended by about 70 teachers of agriculture.

In the opening address Dr. S. S. Cameron, director of agriculture, stated that it was well known that the agricultural education work carried out in Victoria had been somewhat disjointed, and that while the scheme provided apparently offered an opportunity of advancing stage by stage from the elementary school to a university graduation in agricultural science so far there was no instance of such a career having been passed through. The efforts to promote agricultural education among adult farmers by means of farmers classes, lectures, and demonstrations had been only occasionally successful. It was hoped, if this teachers' farm school proved successful, to hold many such schools throughout the year but devoted to specialization in the various distinct phases of agriculture, such as dairying, cereal culture, fruit growing, sheep husbandry, irrigation farming, etc.

A list of the subjects and demonstrations at this school and extracts from a student's notebook are given.

A manual for laboratory and field studies in agriculture, J. M. LECATO (Huntington, W. Va.: Author, 1915, pp. 75, figs. 5).—The 100 exercises in this manual, planned for a year's course consisting of three hours of recitation and four hours of laboratory work a week, relate to forestry, soils, the plant and its propagation, diseases and insect enemies, vegetable gardening, field, forage, and pasture crops, and farm animals, including poultry. The entire equipment necessary for a section of 12 students can be purchased for \$100 or less.

Agriculture for school and farm, I, J. M. NAPIER, W. H. BARTON, and W. P. STEWART (Clemson Agr. Col. S. C., Ext. Div. [Pub.], 1915, July, pp. 129, figs. 35).—This volume consists of a compilation of questions and answers giving simple information on soils, plants, and animals for use in the elementary schools of South Carolina. It is designed to assist the teacher in learning elementary practical agriculture while teaching it and is also suggested as a text for use in farmers' night schools for adults. A dramatization of a dialogue entitled Agriculture and the Farmer is appended.

Elements of farm practice, A. D. and E. W. Wilson (St. Paul, Minn.: Webb Publishing Co., 1915, pp. 347, pl. 1, figs. 153).—This book is a complete revision and extension of the authors' Agriculture for Young Folks (E. S. R., 23, p. 798). It deals largely with common farm practices rather than with scientific principles, and has been prepared primarily for use in rural schools and for elementary classes in other schools. The subjects considered include soils, crops, common weeds and their eradication, the garden, fruit on the farm, plant diseases and insect pests, live stock, feeds and feeding, dairying, poultry, birds, and bees, agricultural engineering, community activities, the farm home, and farm management. Each section is a complete reading lesson followed by questions and examples, so that it may be used to replace a part of the regular reading, language, and arithmetic lessons.

Soils courses at the Iowa State College, P. E. Brown (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 42-47).—A description of the laboratory work in soils at the Iowa College is given, together with a brief statement of the development of the soils work at this institution. Prior to 1902 this consisted of one brief course in soil physics, but in that year was organized as a subdivision of the agronomy department with four distinct courses in soil physics, soil fertility, special problems in soil physics, and special problems in soil fertility. These courses have formed the foundation for the present courses, numbering about 30, for undergraduate and graduate students in agriculture, and classified as soil physics, soil fertility, soil bacteriology, soil surveying, and soil management.

The preparation of material for field crops laboratory, W. O. WHITCOMB (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 38-41, pls. 2).—Suggestions based on a three-year study of the problem at the Montana College, are offered for collecting, pressing, and preparing mounted material for the field-crops laboratory.

Seed testing (Cornell Rural School Leaflet, 9 (1916), No. 3, pp. 403-413, figs. 5).—Directions are given for testing seeds for purity and viability and for making the necessary apparatus.

Laboratory experiments on food products, E. H. S. Balley (Philadelphia: P. Blakiston's Son and Co., 1915, pp. VI+44).—These experiments are designed especially for use with the author's text, The Source, Chemistry, and Use of Food Products (E. S. R., 32, p. 353), but are adapted for use with any course on the composition of food. They deal primarily with the raw and manufactured food materials as found in the field, the market, and the provision store, and enable the student to determine the composition of ordinary food materials and how they are sometimes adulterated and mislabeled.

Twenty lessons on poultry keeping, C. T. Patterson (*Philadelphia and London: J. B. Lippincott Co., 1916, pp. X+92, pl. 1, figs. 55*).—This is an elementary treatise prepared under the direction of the American Poultry Association for the use of teachers and pupils in the public schools. The lessons treat of the origin and history, nomenclature, characteristics, breeds and varieties, judging, enemies and diseases, and care and management of fowls.

Tentative outline of agricultural engineering work for Mississippi agricultural high schools, D. Scoates (Bul. Miss. Agr. and Mech. Col., 13 (1916), No. 1, pp. 20).—Classroom and laboratory work is outlined under the subjects of farm machinery, farm power, farm buildings, surveying and drainage, roads, and rural sanitation. The laboratory outline includes references to exercises previously given by the author (E. S. R., 32, p. 597). An extended bibliography is included.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1915 (U. S. Dept. Agr. Rpts. 1915, pp. V+429).—This contains the reports of the Secretary and heads of bureaus and other administrative officers. The various reports are also issued as separates.

Federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations (U. S. Dept. Agr., States Relations Serv., Federal Legislation [etc.] Affecting Agr. Cols. and Expt. Stas. (1915), pp. 35).—A revision to October 15, 1915, of the circular previously noted (E. S. R., 32, p. 496).

Twenty-eighth Annual Report of Georgia Station, 1915 (Georgia Sta. Rpt. 1915, pp. 20).—This contains the organization list, reports by the president of the board of directors and the director of the station on its work during the year, and a financial statement for the fiscal year ended June 30, 1915. The experimental work reported is for the most part abstracted elsewhere in this issue.

Twenty-eighth Annual Report of Illinois Station, 1915 (Illinois Sta. Rpt. 1915, pp. 27).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1915, brief notes as to the principal lines of work, a list of the publications of the station since its establishment, and a list of those issued during the year.

Director's report for 1915, W. H. JORDAN (New York State Sta. Bul. 413 (1915), pp. 611-652).—This contains the organization list and a review of the work and publications of the station during the year.

Twenty-sixth Annual Report of North Dakota Station, 1915 (North Dakota Sta. Rpt. 1915, pts. 1, pp. 46; [2], pp. 25).—Part 1 of this report contains the organization list, a report of the director, including an extended report on extension work, and a financial statement for the fiscal year ended June 30, 1915. The experimental work reported is for the most part abstracted elsewhere in this issue.

Part 2 comprises the report of the food commissioner on food, drugs, and sanitation, and is abstracted on page 61.

Plan of work for Trumbull County experiment farm, C. W. Montgomery (Mo. Bul. Ohio Sta., 1 (1916), No. 4, pp. 119-122).—The plan of work being followed is outlined.

Monthly bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta., Mo. Bul., 3 (1916), No. 12, pp. 16; 4 (1916), No. 1, pp. 16, figs. 8).—These numbers contain brief articles on the following subjects:

Vol. 3, No. 12.—Some Hog Raising Experiments, by W. A. Linklater (see p. 68); Spring Spraying Suggestions for Western Washington, by J. L. Stahl; The Succulent Feed Supply (see p. 69), by E. B. Stookey; and Care and Management of Baby Chicks (see p. 69), by Mr. and Mrs. G. R. Shoup.

Vol. 4, No. 1.—Trapping Moles and the Possible Utilization of Their Skins, by T. H. Scheffer; Feed and Care of the Calf for the Dairy, by H. L. Blanchard; Tillage, by E. B. Stookey; and Mites and Lice, by Mr. and Mrs. G. R. Shoup.

NOTES.

Arizona University and Station.—On July 1 active work was begun on a new substation in the Salt River Valley consisting of 160 acres in the vicinity of Mesa. This farm will constitute the main point for experimental work in the irrigated part of the State and will be devoted to experiments in horticulture, agriculture, and animal husbandry. A residence, barns, and stock pens are to be constructed.

R. H. Forbes, who has been pursuing graduate work at the California Citrus Station for the past year, received the degree of Doctor of Philosophy from the university in May. P. W. Moore has been appointed assistant in plant breeding.

Arkansas University and Station.—P. B. Barker, associate professor of farm crops in the extension service of the University of Missouri, has been appointed head of the department of agronomy and has entered upon his duties. W. E. Ayres has been appointed assistant in agronomy, chiefly for work in cotton investigations.

California University.—The agricultural extension division is giving a course of 14 agricultural lectures in cooperation with the San Francisco Y. M. C. A., with the object of pointing out to city men and women contemplating a change of occupation from the city to the country certain elementary facts that, when fully considered, should help toward success in the new environment. The attendance at these lectures is ranging between 500 and 550.

The division of landscape gardening and floriculture, in response to a growing demand for suggestions concerning landscape improvement and development of school grounds, has assembled a collection of sketch plans and blue prints representing actual problems in school-ground design as they have been worked out for various schools in the State. Many of the designs are in color, while others are actual working planting plans with plant lists attached. They have been selected primarily to illustrate correct principles of landscape design as they may be applied in the systematic development of school grounds of various sizes. The collection is being sent to educators for study or exhibitions upon request.

According to a note in *Science*, Frank Adams has been appointed professor of irrigation investigations. He will also continue his work with the Office of Public Roads and Rural Engineering of this Department.

Connecticut College.—New England Homestead announces that the Gilbert estate at Georgetown, bequeathed to the college in 1906 (E. S. R., 17, p. 717), is to be opened as a practical farm school. No formal lectures are to be given but practical work will be given in the fields, dairy, poultry plant, and garden. Applicants must be at least 16 years of age and residents of the State. Not more than from 10 to 12 students can be accommodated at present, although it is hoped ultimately to take as many as 30. George Eaton has been appointed principal of the school.

Delaware College and Station.—W. A. Lintner, assistant professor of agronomy and assistant agronomist, has resigned to engage in commercial work.

Georgia College.—Recent appointments include Dr. T. S. Leith as instructor in veterinary medicine, W. O. Collins as instructor in soil chemistry, W. H. Collins as instructor in agronomy, C. N. Wilder as tutor in chemistry, Pope R. Hill as fellow in agronomy, and J. F. Hart, jr., as general field agent in the extension department.

Iowa College.—M. R. Tolstrup, assistant professor of dairying, has been appointed in charge of the department of markets of Vermont in the office of the State Commissioner of Agriculture. The work is to be conducted in cooperation with the Office of Markets and Rural Organization of this Department.

Kansas College.—Chas. L. Quear has been appointed research assistant to President Waters.

Kentucky Station.—W. V. Smith has resigned as assistant animal husbandman, L. R. Himmelberger as associate in hog cholera serum production, and H. K. Wright as assistant in hog cholera work. N. R. Elliott has been transferred from assistant in horticulture to extension work in horticulture and has been succeeded by A. L. Olney. O. S. Crisler and W. H. Simmons have been transferred from the department of diseases of live stock, the former to extension work and the latter as dairy inspector in the food and drug department.

Maine Station.—John A. Perry, William R. Rich, and Walter W. Webber have been appointed assistant chemists beginning July 1, vice Ehner R. Toby, Edward E. Sawyer, and Walter H. Rogers, all of whom have resigned to engage in commercial work.

Massachusetts College.—A conference of Massachusetts bankers was held at the college May 24 and 25 with an attendance of about 40. The object was to present to the bankers of the State information regarding the new outlook for agriculture and its possibilities and significance. President Butterfield, C. W. Thompson, of the Office of Markets and Rural Organization of this Department, and Edward F. Howell, managing director of the New York State land bank, were among the speakers.

Missouri University and Station.—During the university summer session, from June 8 to August 4, 18 courses in agriculture which are accredited in the four-year course and three in forestry will be offered. Of these agricultural courses, nine are required of students for graduation, two of which are farm management field studies. The arrangement makes it possible for the teacher who is a candidate for the degree in agriculture to take all the required courses in agriculture during the summer session. In addition there are general agricultural courses for teachers only.

The number of resident students which have received instruction in the college of agriculture during the present year is 954, of whom 637 are in the four-year course, 266 in the short course, and 51 graduate students.

W. W. Swett has been appointed instructor in dairy husbandry.

Montana Station.—R. R. Dodderidge, assistant in animal husbandry, resigned in May to take up the management of a farm.

Nevada Station.—A detailed technical study is contemplated of the feeding value of the white sage, Eurotia lanata, its manner of spreading and distribution in nature, and methods of management which will restore depleted white sage ranges. A cooperative study of biting flies of cattle on the ranges will also be undertaken this summer, preliminary arrangements having been made with the Bureau of Entomology of this Department.

New Mexico College and Station.—E. H. Divelbiss resigned June 1 as assistant horticulturist in the station to become county agent for Chaves County. J. W. Rigney, until recently county agent for that county, has been appointed assistant horticulturist.

New Jersey Stations.—William S. Porte, research assistant in plant breeding, and W. N. Cowgill have resigned, the former to become instructor in agriculture in the Somerville, N. J., High School. John W. Bartlett, field assistant in horticulture, has been appointed extension specialist in dairy husbandry and has been succeeded by Ralph M. Hubbard. J. B. R. Dickey has been appointed extension specialist in soil fertility, and William H. McCallum state leader of boys' clubs.

Cornell University and Station.—Press reports announce the resignation of Dr. B. T. Galloway as dean and director. H. B. Knapp, extension professor in pomology, has resigned to take charge of the new state school of agriculture of Schoharie County.

New York State Station.—Governor Whitman has approved a bill appropriating \$30,000 toward the construction of a \$100,000 administration, library, and demonstration building. Appropriations have several times been granted for this building by the legislature but have previously been vetoed by the governors.

North Carolina College and Station.—W. C. Riddick, vice-president and professor of civil engineering, has been appointed president of the college. H. L. Cox, assistant chemist in the station, has resigned to engage in commercial work and has been succeeded by L. B. Johnson, a 1916 graduate of the college.

Results recently obtained by the division of animal husbandry at the Iredell substation indicate that it pays to winter sheep in that section on open pasture rather than with corn silage. The cost of wintering the two lots was practically the same, but the ewes wintered on pasture came out in the spring in much more thrifty condition and had made four times as much gain. A corral and shed were found to be necessary for protection at night and in inclement weather.

Ohio State University.—Beginning July 1, the work in soils is to be transferred to the department of agricultural chemistry and the department of agronomy will be abolished. The work in field crops will be maintained as a distinct department. Dr. J. F. Lyman, professor of agricultural chemistry, has been granted a year's leave of absence, a portion of which will be spent in graduate work at Yale University.

Applications for the agricultural correspondence course, offered for the first time this year, numbered 6,348, of whom but 4,644 could be accommodated. An enlargement of the work is planned for the ensuing year.

Oregon College and Station.—At the 1916 summer school, 89 courses are being offered in various college subjects, with 53 members of the faculty, as well as outside specialists, scheduled as regular instructors, lecturers, and officers.

At the Southern Oregon substation a study of pear blight resistance is being carried on under the direction of F. C. Reimer. He is said to have secured, with the assistance of other station authorities, the largest and most comprehensive pear variety collection in the country.

The uniform marketing plan for horticultural products, suggested by the Office of Markets and Rural Organization of this Department, is to be put into operation in Oregon under the direction of the college, assisted by the Portland Chamber of Commerce. The work of organization will be conducted for the college by Dr. Hector MacPherson, head of the bureau of farm organization and management. The physical handling of the fruit and vegetables will be in charge of Prof. C. I. Lewis. An active campaign is now under way to enlist the growers in this movement.

Pennsylvania College and Station.—Ambrose N. Diehl, of Duquesne, and A. W. Mitchell, of Erie, have been appointed to the board of trustees, vice Andrew Carnegie and William H. Walker. C. W. Larson, head of the department of

dairy husbandry, and M. F. Grimes, assistant in animal husbandry, have resigned, the former to accept a position with Columbia University and the latter a position with the Delaware College. Recent appointments, effective July 1, include E. R. Hitchner as instructor in bacteriology, and W. W. Wood as instructor in agricultural extension; and effective September 1, J. W. Miller as teaching fellow in botany, and G. M. Shisler as assistant in agricultural chemistry.

Porto Rico College.—R. L. Clute, for about thirteen years instructor in agriculture in the Philippine Normal School and agricultural inspector at Manila from 1907 to 1911, has been added to the agricultural faculty.

Tennessee University and Station.—The forty-third annual meeting of the East Tennessee Farmers' Convention was held at the station May 16 to 18 with a total attendance of about 4,000. Following the convention a sale of Aberdeen-Angus cattle was held under the auspices of the American Aberdeen-Angus Breeders' Association, 47 animals bringing an average price of \$243. This is the second public sale held in conjunction with the convention and the first of this breed. H. R. Duncan, instructor in animal husbandry, resigned June 15 to engage in farming.

Virginia College and Station.—Dr. A. W. Drinkard, jr., associate horticulturist, has been appointed director of the station. W. J. Schoene, acting director for the past two years, will continue as state entomologist and entomologist of the station. Jesse M. Jones, of the States Relations Service of this Department, has been appointed director of the extension service.

West Virginia University and Station.—A tract of land, comprising about 20 acres adjoining the station farm, has been purchased for development as a poultry plant. This will be available for instruction purposes in the college of agriculture, as a source of eggs and fowls in connection with boys' and girls' club work, and for poultry studies in the station.

Wyoming University and Station.—So much demand has been expressed by sheep men of Wyoming for special help in their problems that the college of agriculture has arranged to have Prof. John A. Hill devote one-half of his time to extension work in this field.

Director H. G. Knight, now on leave of absence for research work at the University of Illinois, will return to the station September 1. Dr. S. K. Loy, half time research chemist, will be transferred entirely to instruction work on the same date. Dr. E. H. Lehnert has been appointed station veterinarian vice Dr. O. L. Prien.

Convention of Milk Producers and Other Dairy Interests of the United States.—This convention was held in Washington, D. C., May 5 and 6, under a call issued by the National Dairy Council and the National Dairy Union. About 200 delegates from 31 States were in attendance, representing 91 dairy, live stock, and farm organizations. The object of the conference was announced as "to develop uniform practical regulations governing the production and care of dairy products." William T. Creasy, secretary of the National Dairy Union, served as temporary chairman of the conference, and M. D. Munn, president of the National Dairy Council, was chosen permanent chairman, N. P. Hull, president of the National Dairy Union, vice-chairman, and Mr. Creasy, secretary.

In the opening address Mr. Creasy called attention to various problems confronting the dairy interests of the country. He advocated the formation of a national council of all agricultural interests with headquarters at Washington.

An address of welcome was made by Hon. Carl Vrooman, Assistant Secretary of Agriculture, in which he spoke especially of the benefits of government regulation. Such regulation, in his opinion should be based upon the fundamental principle that the public interests are paramount to any private interests, and

should be practical, discriminating, and well digested. Mr. Munn responded to this address, outlining some of the work of the conference and discussing the relations of this Department with the dairy interests of the country.

The address of Mr. Hull urged farmers and dairymen to take a more active part in shaping the regulations that surround their business. He cited as handicaps to profitable milk production the lack of uniformity in milk regulations and methods of inspection and the high cost of distributing milk and cream.

Dr. H. A. Harding, of the Illinois University and Station, discussed the standardization of conditions under which milk and cream are handled from the producer to the consumer, particularly as affecting interstate shipment. He maintained that clean milk could be produced under relatively inexpensive conditions, referring to recent studies indicating that the barn and the cow are relatively unimportant sources of bacteria in dairy products as compared with the dairy utensils and the maintenance of proper temperatures during milk transportation.

In an address on Pasteurization in the Dairy Industry, Prof. O. F. Hunziker, of the Purdue University and Station, contended that the integrity and future progress of the dairy industry depend upon pasteurization. He reviewed experiments showing that pasteurization at 145° F., holding process, somewhat improved the digestibility of milk, and that pasteurization at low temperatures accentuates and deepens the cream line and hastens the rising of cream. The pasteurization of both milk and cream he deemed largely an economic question, as pasteurized milk may be more easily kept sweet until placed in the consumer's pantry and pasteurized cream produces butter of better quality.

B. H. Rawl, chief of the Dairy Division of this Department, discussed the Utilization of Surplus Dairy Products. He stated that only a few localities have a surplus at present, but that the rapid growth of the industry makes it necessary to give consideration to methods for increasing the demand. He called attention to the desirability of building up an export business and described in detail methods of increasing domestic consumption. He advocated developing the cheese industry in sections suitable for the business, such as the irrigated regions of the West and the mountainous sections of the Southeast, and pointed out opportunities for high-grade butter and milk production.

W. J. Kittle, secretary of the Northern Illinois Milk Producers' Association, L. J. Taber, master of the Ohio State Grange, and J. J. Farrell, Dairy and Food Commissioner of Minnesota and president of the National Creamery Buttermakers' Association, discussed forms of legislation, milk regulations, and inspection problems. G. L. McKay, secretary of the American Association of Creamery Butter Manufacturers, considered Legal Standards for Butter.

Resolutions were adopted by the convention favoring immediate and comprehensive studies by this Department and the experiment stations of contagious abortion, measures to control more fully tuberculosis in dairy herds, and the formation of a bureau or office in this Department to deal exclusively with dairy cattle and the dairy industry. The appointment by the Secretary of Agriculture of a committee of producers, dealers, and sanitary officers to frame a set of rules and regulations covering milk production and handling and to urge their adoption by States and cities was also favored. Other resolutions advocated the labeling of all dairy products in the production of which foreign fats had been used, experimentation with denatured alcohol, and the closer union of agricultural interests in cooperative legislative effort.

Series of Lectures on Nutrition.—A series of illustrated lectures on nutrition was given under the auspices of the Washington Academy of Sciences at the New National Museum as follows: April 7, The Basal Food Requirements of Man, by Dr. Eugene F. Du Bois; April 14, Nutrition and Food Economics, by

Dr. Graham Lusk; April 21, Investigations on the Mineralogical Metabolism of Animals, by Dr. E. B. Forbes; and April 28, The Relation of Vitamins to Nutrition in Health and Disease, by Dr. Carl Voegtlin.

New Journals.—The Journal of Bacteriology is being published bi-monthly as the official organ of the Society of American Bacteriologists. It will contain original articles and abstracts of papers read at meetings of the society and of other bacteriological literature.

The papers in the initial number include The Genesis of a New Science—Bacteriology, by W. T. Sedgwick; The Pedagogics of Bacteriology, by D. H. Bergey; Further Studies on Bacterial Nutrition; The Utilization of Proteid and Nonproteid Nitrogen, by L. F. Rettger, N. Berman, and W. S. Sturges; Studies on Soil Protozoa and Their Relation to the Bacterial Flora, I, by J. M. Sherman; A Culture Medium for Maintaining Stock Cultures of the Meningococcus, by G. G. A. Roos; and Bile Compared with Lactose Bouillon for Determining the Presence of *B. coli* in Water, by M. M. Oost.

Addisonia is a new quarterly journal published by the New York Botanical Garden under a bequest by the late president of the garden, Judge Addison Brown. This bequest provides for the establishment and maintenance of a magazine to be devoted exclusively to the illustration by colored plates of the plants of the United States and its territorial possessions, and of other plants flowering in the garden, together with brief popular descriptions and similar data. The initial number contains plates and descriptions of 10 plants.

Miscellaneous.—At a recent meeting of the State Commissioners of Agriculture and others, held in Washington, D. C., a permanent organization was effected under the name of National Conference of Commissioners of Agriculture and the following officers: President, E. J. Watson, of South Carolina; vice-president W. P. Guptil, of Maine; and secretary-treasurer, Clarence J. Owens, of Washington, D. C.

The department of physics at the Ontario Agricultural College has been divided, W. H. Day continuing at the head of the department, and in charge of studies of evaporation, cold storage, farm power, farm water supply, ventilation, etc. J. R. Spry has been appointed in charge of the farm drainage campaign.

Dr. Alfred E. Cameron, of the University of Manchester, has been appointed field officer of the entomological branch of the Canadian Department of Agriculture, and will study pear thrips and other insects in British Columbia.

Prof. William J. Beal, formerly professor of botany at the Michigan College, was granted the degree of doctor of agriculture by Syracuse University at its recent commencement.

EXPERIMENT STATION RECORD.

Vol. 35.

AUGUST, 1916.

No. 2.

Since the passage of the Smith-Lever Extension Act in 1914, no agricultural question, among the many pending before Congress, has aroused more widespread interest than that of the provision of more adequate rural credit facilities. During this period, scores of bills, embracing a broad range of remedies, have been proposed. Commissions, both State and National, official and unofficial, as well as the United States Government, the agricultural colleges, organizations, and individuals have studied the subject in its various phases in this country and abroad. At length, public opinion has sufficiently crystallized to make possible the enactment of a law designed to initiate a Federal system of rural credit based upon farm real estate, and the result is the Federal Farm Loan Act, approved July 17 by President Wilson.

The passage of legislation of this sort constitutes a notable recognition of American agriculture in a new direction. By the establishment of the Federal Department of Agriculture and the system of agricultural colleges and experiment stations and the provision, for many years, of large appropriations to carry on and extend the activities of these institutions, the principle of Federal aid to agriculture through such means as education, systematic research, and the demonstration of improved methods has become firmly accepted. The new legislation, however, recognizes more definitely than ever before that agriculture is a basic industry, one in which knowledge and skill alone are not sufficient for success, and that it is highly important that farmers obtain the capital they need on terms consistent with their credit.

That they have not always been able to do this was indicated by President Wilson in his message of December 7, 1915, advocating the provision of "adequate instrumentalities on which long credits can be obtained on land mortgages," and likewise in a speech made when signing the Act, in which he said: "The farmers, it seems to me, have occupied hitherto a singular position of disadvantage. They have not had the same freedom to get credit on their real assets that others have had who were in manufacturing and commercial enterprises,

and while they sustained our life they did not in the same degree with some others share in the benefits of that life." The creation by the Federal Government of a distinctive rural credit system is thus a recognition of the needs of agriculture in this direction, and an indication of the belief that to render assistance in meeting these needs will be to fulfill a function which will "promote the general welfare."

Although the machinery through which it is proposed to carry on the new system does not directly include the agricultural colleges and experiment stations, many agricultural economists and other college and station workers have been active in studying the problem, and the passage of the Act is to them, as to all associated with agriculture, an event of much interest. This could not be otherwise, in view of their close touch with farm life. Instruction staffs engaged in preparing students for agricultural service have repeatedly been brought face to face with the obstacles confronting their graduates who wish to farm but have only limited capital. Experiment station and extension workers have often been handicapped in recommending such sound and simple remedies for specific problems as an increase in the farm business by the purchase of additional land or live stock, the drainage of wet areas, the construction of a silo, and the like, by a realization of the impossibility of the farmers securing the necessary capital without excessive interest rates and commissions, uncertainty as to the renewal of short-term mortgages, and kindred difficulties.

The provision of adequate rural credit facilities would thus widen the opportunities of the college and station staffs for usefulness, and render their work more effective and far-reaching. Many of the undertakings for which the farmer will wish to utilize his new resources will involve matters with which he is unfamiliar, such as the details of silo construction or of farm drainage or the selection of pure-bred live stock, and he will often turn to the county agent for assistance. In some cases the borrower's plans may not be of the wisest, and the adviser must endeavor to prevent extravagance and waste. Thus the introduction of a new system will bring its own problems to the colleges and stations, and upon them, accordingly, will rest a measure of responsibility for its success.

The history of the movement resulting in this legislation is interesting, partly from the fact that it is of such comparatively recent origin. It is one of many evidences of a new viewpoint and attitude toward the business of farming.

With the passing away of what may be termed the pioneer or formative period of American agriculture toward the close of the nineteenth century, the need of an efficient system of financing agri-

culture began to be more and more realized. By this time free land had largely disappeared, and land values began to be more definite and stable. Farmers came to appreciate the value of well-planned irrigation or drainage programs, systems of clearing and improving land, more definite systems of road construction, proper building programs, and better and more equipment on farms. The lack of funds in many sections with which to carry out these and other projects of obvious advantage emphasized and strengthened the demand for more adequate credit facilities.

According to the Census of 1910, 33.6 per cent of farms operated by their owners in the United States were mortgaged. The mortgages averaged \$1,715 each, or 27.3 per cent of the value of the land and buildings of the farms mortgaged. The total amount of the mortgages on farms operated by their owners was slightly over 10 per cent of the value of the land and buildings of all farms of this class. On this basis the aggregate farm mortgage indebtedness of the country has been estimated to be about \$3,600,000,000. An inquiry instituted by the United States Department of Agriculture in 1913 indicated that of this amount about one-fifth was supplied by banks, about one-fifth by life insurance companies, and the remainder by mortgage companies and private individuals. A large part of this sum was loaned for relatively short periods, usually from three to five years. Much variation in interest rates and commissions was found in the different sections of the country. Department reported a range in the percentage of the farm mortgage business on which commissions were paid from 1.3 per cent of the total in Connecticut to 91.6 per cent in Oklahoma, and an average rate for interest and commission ranging from 5.3 per cent in New Hampshire to 10.5 per cent in New Mexico. In many individual cases the rates for interest and commission were far in excess of these figures.

In 1910, the American Bankers' Association appointed a committee to study the general subject of farm finance in this country. The report of the Secretary of Agriculture for 1912 contained the results of a questionnaire sent out to country bankers, farmers, and merchants as to the prevailing local conditions, while in the same year the collection of data as to European methods was undertaken by the State Department and some of its findings submitted by President Taft to the House of Governors.

In April, 1912, a conference on cooperative credit was held at Nashville, Tennessee, under the auspices of the Southern Commercial Congress. This congress undertook to assemble a commission of representatives from each State to study cooperative systems in Europe. The commission was known as the American Commission, and consisted of sixty-seven members from twenty-nine States, the District

of Columbia, and the Dominion of Canada. Early in 1913 it was supplemented by the United States Commission of seven members, authorized by Congress to work in cooperation with it, as previously noted (E. S. R., 28, p. 301). A three months' study was made by the two commissions of agricultural credit and cooperation in fourteen countries of Europe, followed by elaborate reports and the submission of a proposed land credits bill.

The first Federal legislation providing improved rural credit facilities was embodied in the Federal Reserve Act of December 3, 1913. This Act contained more liberal provisions than had previously obtained as to the discounting of agricultural short-time loans, and also empowered the national banking associations, under certain restrictions, to make loans on improved and unencumbered farm land. These real estate loans were, however, restricted to 50 per cent of the value of the property and in duration to five years.

In March, 1915, the Senate and House each adopted a rural credits amendment to the agricultural appropriation bill, but in conference both of these propositions were eliminated and a joint congressional committee provided to study the subject further and suggest legislation. This committee subsequently submitted a bill which, after amendment, passed the Senate May 3, and the House May 15, 1916. After a considerable period in conference, the measure became a law July 17. It is evident, therefore, that the legislation is not hasty but that time has been taken for study of the question and the adaptation of a system to American conditions.

The complete title of the new measure is "An act to provide capital for agricultural development, to create standard forms of investment based upon farm mortgage, to equalize rates of interest upon farm loans, to furnish a market for United States bonds, to create Government depositories and financial agents for the United States, and for other purposes." This title indicates its general scope and comprehensiveness.

The act provides for a Federal Farm Loan Board, a system of Federal land banks, National farm loan associations, and joint-stock land banks. Some of these component parts correspond to a certain extent to institutions which have proved successful in Europe and elsewhere, and some of the principles incorporated are analogous to those followed in many of the building and loan associations developed in numerous urban sections of this country. In form the measure is also patterned in a general way after the Federal Reserve Act, and while the system proposed is essentially distinct as to administrative purposes it is designed to supplement and articulate with the Federal reserve system.

The Federal Farm Loan Board is given supervision over a Federal Farm Loan Bureau, to be established in the Treasury Department and to have charge of the execution of the act. The board is to consist of the Secretary of the Treasury, ex-officio, and four other members to be appointed for terms of two, four, six, and eight years, respectively, in the beginning, and thereafter of eight years each, at salaries of \$10,000 per annum. The initial appointments consist respectively of Messrs. Charles E. Lobdell, of Kansas; George W. Norris, of Pennsylvania; William S. A. Smith, of Iowa; and Herbert Quick, of West Virginia. One of these members is to be designated as the farm loan commissioner, and will be the active executive officer of the board. The board is to charter the Federal land banks, the National farm loan associations, and the joint-stock land banks, and has general supervision and control over the entire system. It is also to prepare publications relative to the act, the principles of rural credit, and the like, and to disseminate its results, through the United States Department of Agriculture or otherwise.

The United States is to be divided by the board on a basis of State lines and the farm loan needs of the country into twelve land bank districts. Each district may contain a Federal land bank and branch offices as needed. A capital stock of \$750,000, divided into shares at \$5 each, is required for each of these banks, but it is provided that if this is not subscribed by the public within thirty days the Government must purchase the unsubscribed portion of the stock. The funds thus secured, together with a special appropriation of \$100,000 for the expenses of the farm loan board, are expected to be available to initiate the new system.

The National farm loan associations, which are distinctive local organizations, are to be chartered by the Federal farm loan board upon the recommendation of the district land bank. Membership in these associations is restricted to actual or prospective owners of farms in a given locality who wish to borrow upon farm mortgage security. At least ten such persons are required and their individual borrowings must not be less than \$100 nor more than \$10,000 and must aggregate at least \$20,000.

The loans when granted are made by the district land bank to the individual members of the association through its secretary-treasurer. The amount can not exceed 50 per cent of the value of the land, based principally on its earning power, plus 20 per cent of the value of the permanent insured improvements. The loan can be negotiated only for the purpose of purchasing land for agricultural uses, the purchase of equipment, fertilizers, and live stock necessary for the farm operations, the provision of buildings or the improvement of farm lands or the liquidation of existing indebtedness.

Loans are to be made upon first mortgage security, for periods of from five to forty years, with interest at not to exceed 6 per cent, and with payments on the amortization plan. This provision is intended not only to enable the farmer to secure loans conveniently and at rates he can afford, but to protect him in these loans from the necessity of heavy costs, bonuses, and commissions, and to extend the period of payment over a long period of years without the necessity of uncertain and costly renewals at stated periods. At the same time, opportunity is given for payments, in addition to those required, on installment dates after the expiration of five years, thereby encouraging thrift and allowing the borrower to profit by favorable conditions.

In order to obtain funds to make the loans, the Federal land banks, upon the approval of the farm loan board, are empowered to issue farm loan bonds based upon the mortgages obtained through the farm loan associations. These bonds may be issued in denominations ranging from \$25 to \$1,000 and in series of at least \$50,000, and are to bear interest payable semi-annually at a rate not to exceed 5 per cent per annum.

The farm loan associations are essentially mutual and cooperative, each member being required to subscribe for stock to the extent of 5 per cent of his loan. This stock is held by the association as collateral security until the payment of the loan, at which time it is retired at par. In the meantime the borrower has received his proportionate share of any dividends from the operations of the association. A similar arrangement is also required between the associations and the Federal land banks.

Shareholders in the associations are held individually responsible, equally and ratably, but not for one another, for the liabilities of the association to the extent of the par value of their stock, plus the amount paid in and represented by their shares. It is, therefore, a plan for limited liability of members as contrasted with the assumption of unlimited liability which constitutes an essential feature of a number of the European systems.

Inasmuch as inability to organize farm loan associations might work hardship upon individual borrowers, provision is also made whereby, after the act has been in effect a year, the Federal land banks may make loans through other channels. If no farm loan association has been, or is likely to be, formed in a locality the land bank may employ an incorporated bank, a trust company, a savings institution, or a mortgage company as its agent in arranging the loans and in collecting payments. The agent must endorse all loans negotiated and may receive actual expenses and a commission not to exceed 0.5 per cent per annum. The borrower in these cases sub-

scribes for stock in the land bank itself and receives dividends accordingly.

Another alternative is provided in the joint-stock land banks. These banks are to possess some powers similar to those of the Federal land banks, but differ from them in a number of ways. They must have a subscribed capital of at least \$250,000, none of which comes from Government funds. These banks are allowed to make loans on first mortgages on farm lands, and to issue a distinctive series of farm loan bonds to an amount not exceeding fifteen times their capital and surplus. Their interest rate can not exceed by more than one per cent the rate charged on their land bonds, or a total of 6 per cent, and any commissions collected must have the approval of the farm loan board. In making the loans the joint-stock land banks, however, need not restrict the purposes for which the loans are to be used or the amount to an individual, or require the borrower to be personally engaged in the cultivation of the land mortgaged. The banks are also noncooperative, no stock subscriptions being required of borrowers and any profits being apportioned among the shareholders alone.

The mortgages received and the bonds issued under the authority of the act, whether by the Federal land banks or the joint-stock banks, are specifically exempted from Federal, State, and local taxation. The bonds are also made legal investments for all fiduciary and trust funds, and may be bought and sold by member banks of the Federal reserve system. It is expected that, because of these advantages and their standardized character, these securities will prove attractive investments and thus provide the bulk of the funds to be loaned under the system.

The new act may well lead to an expansion of the influence of the agricultural colleges and experiment stations, and constitute an aid in putting into effect better methods and practices. It should make it practicable for a larger proportion of college graduates to engage in farming. It should also make the work of the county agents more effective, and give an increased impetus to the work of investigation which aims at improvements to be inaugurated by the individual farmer. At all events, it is a response to a widespread demand arising from what is believed to be a necessity, and a logical step toward better agriculture and better farming conditions. Operations under its provisions will, therefore, be awaited with keen and widespread interest.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

The starches of the grain sorghums, C. K. Francis and O. C. Smith (Oklahoma Sta. Bul. 110 (1916), pp. 3-38, figs. 21).—This bulletin reports the results of a detailed microscopical study of the grain sorghums. The apparatus and methods used for making the photomicrographs are described in detail. A new apparatus devised by the authors for the determination of the gelatinizing temperature of the starches by means of a thermo-slide is also described in detail and illustrated by drawings.

The quantity of starch found in the different sorghums was fairly uniform, Kafir corn containing 63.6 per cent, White mile maize 64.8, Yellow mile maize 63.1, feterita 63.8, and darso 63.7 per cent.

The following averages of triplicate determinations of the gelatinizing temperatures of the various starches are submitted: White kaoliang, 78° C.; Brown kaoliang, 76.3°; feterita, 75.5°; Orange Cane sorghum, 72.4°; Red Kafir corn, 75°; White Kafir corn, 72.2°; Pink Kafir corn, 64.7°; White milo maize, 74.1°; Yellow milo maize, 76.9°; darso, 72.9°; and Sudan grass, 72.5°. The results obtained by the new thermo-slide procedure checked very closely with those obtained by the water-bath methods.

Photomicrographs, together with detailed descriptions of the following characteristic reactions of the starch grains are submitted: Chloral-hydrate iodin, chromic acid, ferric chlorid, gentian violet, pyrogallic acid, and safranin reactions. The starches examined were those of the White, Red, and Pink Kafir corn, White and Yellow milo maize, Brown and White kaoliang, feterita, darso, Sudan grass, Orange Cane sorghum, corn, sweet potato, Irish potato, rice, arrowroot, navy bean, and wheat.

Tables submitting data of the comparative size of the starch granules of the grain sorghums and the comparative staining values of various starches are included.

It is indicated that "feterita, the milos, and Kafir, containing about 64 per cent starch, seem to be especially suitable as raw materials for the manufacture of high-grade starch by the commercial processes, and if they are used will require practically no change in the machinery now in common use for manufacturing starch from corn."

The variations of gluten, MARCHADIER and GOUJON (Ann. Sci. Agron., 4. ser., 4 (1915), No. 1-6, pp. 7-19).—The composition, changes, and variations in amount of gluten in various flours are briefly discussed.

It is indicated that when rye flour is added to wheat flour the amount of gluten is diminished, while the acidity is greatly increased. Rye flour which yields no gluten possesses a normal acidity ten times greater than that of wheat flour. Acetic acid oxidizes and dehydrates gluten, and when a wheat flour which yields a gluten-gliadin ratio of 1:3 is treated with this acid a gluten with a ratio of 1:1 is obtained.

Development of sugar and acid in grapes during ripening, W. B. Alwood ET AL. (U. S. Dept. Agr. Bul. 335 (1916), p. 28).—Continuing the work previously noted (E. S. R., 25, p. 504) this bulletin embodies the results of a further

and more extended examination, during 1911 and 1912, of the changes in the sugar and acid content of several varieties of grapes. The examinations were made at Sandusky, Ohio, and Charlottesville, Va.

Analytical results obtained from the juice samples submitted indicate that "the total acid percentage is practically the same in the green fruit of Concord in both juice and whole-fruit samples, and this relation continues so nearly throughout the entire period that either result may be taken as fairly expressing the content. The total acid is decidedly higher in the juice sample of green Catawba than in the whole fruit for the first three samples taken; then the acid content of both samples becomes about what may be expected of check samples.

"The results for total tartaric acid in the juice and whole fruit are not so uniform as for total acid. Yet for the Concord samples . . . there is a degree of uniformity which is striking, considering the difficulty of sampling. . . . The Catawba samples show much difference in the green fruit, but the later samples approach uniformity.

"There is a striking dissimilarity in the percentage of tartaric acid for the Concord samples at Sandusky and Charlottesville throughout the period of investigation. Those taken at Sandusky show much less variation than the Charlottesville samples and the former show approximately the same amount at the close of the season as for the partly colored samples first taken, while the Charlottesville samples show a very marked decline in tartaric acid for both the juice and fruit samples. . . .

"It would appear that the crushed fruit invariably yields decidedly the greater part of the free tartaric acid content when pressed. . . . These results support our previous determinations and show that the Concord juice loses free tartaric acid more completely than the Catawba.

"The results for cream of tartar show that in every instance save one the juice sample carries a smaller percentage of cream of tartar than the whole fruit.... The excess, in per cent, of cream of tartar in the whole fruit is sufficient to support a previous statement that this substance exists as crystals and that some of these are retained in the pulp when the fruit is pressed.

"The constant increase of cream of tartar both in the juice and fruit samples follows naturally from the disappearance of free tataric acid."

The composition of the whole fruit was also studied. "The volume and weight of the Concord berries did not show marked changes in size of the fruit throughout the period of the examinations of the samples, but for Catawba there was a decided increase of about 39 per cent in volume and about 44 per cent in weight. It appears that this late-maturing variety for that season shows considerable change in size and weight of berries during the period from coloring to maturity.

"On calculating the actual weight of acid in grams present for each sample of 100 berries examined there is shown in a positive manner... a fairly constant diminution in total weight of this ingredient.... There are some apparently abnormal results; that is, during some periods the actual weight of acid increased slightly, yet this is invariably reversed for the subsequent analysis and the comparison of the first samples and the last taken show a positive loss in total weight of acid present in 100 berries for all the crops analyzed. The data appear to establish the fact that there is a very decided loss in total weight of acid as the fruit ripens."

The analytical data are presented in detail in tabular form.

The urease of soy beans, W. C. DE GRAAFF and J. E. VAN DER ZANDE (Chem. Weekbl., 13 (1916), No. 10, pp. 258-264).—From the results of their investiga-

tions the authors conclude that, although bacteria may be present in soy beans, this is not invariably the case. *Urobacillus pasteurii* could not be isolated. The strong ureolytic action of the soy bean can not be attributed solely to bacteria, since sterile beans still possess a very strong urea-splitting power. A urease must, therefore, be present.

On account of the great variety of soy beans it is possible that some may not contain urease.

On the presence of urease in soy beans, J. T. GBOLL (Chem. Weekbl., 13 (1916), No. 10, pp. 254, 255).—Experimental evidence demonstrating the presence of a urea-splitting enzym in the soy bean is submitted. The use of sterilized beans excluded the possibility of bacterial action on the urea. The results are contrary to those of Mom (see p. 112).

The preparation of anhydrous alcohol, L. W. WINKLER (*Ztschr. Angew. Chem.*, 29 (1916), No. 5, Aufsatzteil, p. 18).—Commercial "absolute alcohol" contains about 1 per cent of water. To obtain perfectly anhydrous and ammonia-free alcohol the author proceeds as follows:

Metallic calcium shreds are thoroughly shaken on a sieve of medium mesh, by which process most of the adhering calcium nitrid is removed. To free the calcium from the oil it is thoroughly washed with carbon tetrachlorid and then dried in a stream of moisture-free carbon dioxid until the odor of carbon tetrachlorid is no longer perceptible. The alcohol is then distilled over the calcium prepared in this manner, using about 20 gm. of the metal to 1 liter of alcohol. To completely remove the ammonia from the anhydrous distillate it is treated with alizarin (several centigrams per liter) and in 10 cc. of this solution 0.5 gm. of tartaric acid is dissolved. This tartaric acid solution is added to the main distillate until there is a complete color change from reddish blue to pure yellow, when a slight excess of the acid solution is added and the alcohol finally distilled in a moisture-free atmosphere.

A simple cell for the determination of hydrogen ion concentration, J. H. Long (Jour. Amer. Chem. Soc., 38 (1916), No. 4, pp. 936-939, flg. 1).—A simple and inexpensive apparatus is described in detail.

A comparative study of aeration and heat distillation in the Kjeldahl method for the determination of nitrogen, K. G. Falk and K. Sugiura (Jour. Amer. Chem. Soc., 38 (1916), No. 4, pp. 916-921).—From their investigation the authors conclude that the aeration procedure in the ordinary Kjeldahl method very often gives inaccurate and unreliable results and is therefore not to be recommended for use.

A study of indicators for the determination of temporary hardness in water, J. F. Nobton and H. I. Knowles (Jour. Amer. Chem. Soc., 38 (1916), No. 4, pp. 877-884).—Experimental data submitted indicate that dimethylamidoazobenzene is the most satisfactory indicator for use in titrating bicarbonate alkalinity (temporary hardness) of natural waters. In the presence of alum lacmoid gives the best results but yields low results in the determination of bicarbonates. For low alkalinities the difference, however, is negligible.

The following standard is recommended: To 100 cc. distilled water 0.1 cc. of an alcoholic solution of dimethylamidoazobenzene is added (2:1,000, and 0.4 cc. normal sulphuric acid. The unknown solution containing the same amount of indicator is titrated until the color matches that of the standard.

Material for uniform laws regarding foodstuffs, IV-VI (Entwürfe zu Festsetzungen über Lebensmittel. Berlin: Julius Springer, 1913, No. 4, pp. VIII+30; 1915, Nos. 5, pp. 33; 6, pp. 24; sups. to Ztschr. Untersuch. Nahr. u. Genussmil., 26 (1913), No. 6; 29 (1915), Nos. 9 and 10).—The first of these pamphlets describes the various kinds of cheese, together with their prescribed requirements, outlines analytical methods for the determination of water, ash,

fat, preservatives, and starch, and considers the interpretation of analytical results. The second pamphlet describes the various kinds of coffee, outlines the methods for the determination of extraneous material, water, ash, water-soluble extractives, caffein, artificial coloring matter, sugar and other carbohydrates, fat, crude fiber, protein, borax, and arsenic-containing shellacs, and considers the interpretation of the analytical results.

The various coffee substitutes are described in the third pamphlet and the prescribed requirements for such material outlined. Analytical methods for the determination of sugar, mineral oils, and glycerin are described, as well as some methods described in the pamphlet on coffee. The microscopical examination is also considered in some detail.

The determination of volatile oil in liqueurs, L. Ronnet (Ann. Falsif., 9 (1916), No. 87, pp. 14-16).—The author outlines a method for the determination of the essence in a liqueur, based on the determination of the iodin value, and gives the procedure for calculating the amount of essence present from the iodin value obtained.

The determination of the volatile oils in liqueurs, C. F. MUTTELET (Ann. Falsif., 9 (1916), No. 87, pp. 17-22; Ann. Chim. Analyt., 21 (1916), No. 3, pp. 50-55).—A gravimetric method for the determination of volatile oils is described in detail.

Determination of the quantity of fat in cream, L. LINDET (Ann. Sci. Agron., 4. ser., 4 (1915), No. 1-6, pp. 1-6).—This material has been previously noted from another source (E. S. R., 34, p. 714).

Determination of stearic acid in butter fat, E. B. Holland, J. C. Reed, and J. P. Buckley, Jr. (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 3, pp. 101-113, figs. 2).—A crystallization method devised at the Massachusetts Experiment Station is outlined as follows:

Five-tenths of a gram of melted insoluble acids is placed in an 8-oz. sterilizer bottle and 150 cc. of an alcohol-stearic-acid solution (3 gm. to 1,000 cc.), accurately measured with a pipette at 30° C., added. The bottle is sealed with a solid rubber stopper, shaken at a gradually increasing temperature until a clear solution is obtained, placed immediately in a pocket of the ice tank, and allowed to stand overnight. The following morning the solution is gently agitated by inverting the bottle several times, and in the afternoon it is siphoned off as thoroughly as possible by means of a small thistle tube and a perforated rubber stopper, using suction. The residue is dissolved in ethyl ether, transferred to a tared 140 cc. wide-mouth Erlenmeyer flask, the ether carefully distilled off, the residue dried at 100°, and weighed.

The construction of a constant-temperature tank, also devised by the authors and used for the crystallization of the stearic acid, is described in detail.

From the molecular weight determinations the crystalline precipitate obtained from butter fat was shown to be pure stearic acid and not a mixture. In studying the influence of various fatty acids on the precipitation of the stearic acid, lauric, myristic, and oleic acids, even in relatively large amounts, showed no appreciable effect. Palmitic acid, however, noticeably increased the solubility and affected the crystalline structure of the precipitate.

Analytical data obtained by the application of the proposed method to the determination of the stearic acid in the insoluble acid in butter fat and beef tallow are submitted in detail. The results indicate a higher percentage of stearic acid in the insoluble acids of butter fat than has been reported by earlier investigators. The concordant results obtained, however, and the close agreement of the molecular weight determinations of the crystalline product with the theoretical, indicate the identity and approximate purity of the stearic acid.

The determination of the iodin number of essential oils, R. MARCILLE (Ann. Falsif., 9 (1916), No. 87, pp. 6-11, figs. 2).—Experimental data as to the iodin numbers of various essential oils and oils used as adulterants, together with their refractive indexes, are submitted in tabular form. The effect of light on the iodin absorption was studied and the results are expressed graphically.

The iodin value of the oils in liqueurs can be determined without first distilling the alcohol, and is a valuable method for detecting adulteration in such

products.

The detection and determination of benzoic acid in animal foodstuffs, K. Baumann and J. Grossfeld (Ztschr. Untersuch. Nahr. u. Genussmtl., 29 (1915), No. 10, pp. 397-409).—After reviewing the methods commonly used for the detection and determination of benzoic acid the authors outline a procedure for which they claim excellent results. This method consists essentially of converting any free benzoic acid in the material to the alkali salt by treatment with dilute alkali, precipitation of the alkali soaps thus formed with calcium chlorid, precipitation of the protein with phosphotungstic acid, extraction of the benzoic acid from the clear filtrate, and, finally, determining the acid either colorimetrically or by titration with standard alkali. Carbon tetrachlorid was found to yield excellent results as an extraction agent.

Experimental data obtained from the application of the method to the determination of benzoic acid in milk, lard, butter, margarin, and cacao fat are submitted which indicate the accuracy of the method.

Critical observations on the qualitative and quantitative determination of saccharin and a new procedure for its qualitative determination, M. Klostermann and K. Scholta (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 31 (1916), No. 3, pp. 67-78).—Earlier methods used for the determination of saccharin are briefly reviewed. A proposed procedure is described in detail and the theory of the reaction discussed. The reaction is sensitive to 1 mg. of saccharin and is more specific than the others commonly used.

The quantitative determination of urea, C. P. Mom (Chem. Weekbl., 18 (1916), No. 3, pp. 72-75).—A method for the determination of urea in urine, using Urobacillus pasteurii, is described. The urea-splitting power of the soy bean is not attributed to the presence of a urease, but rather to bacterial action.

The chemical composition and evaluation of lime-sulphur solutions, J. Bodnár (Chem. Ztg., 39 (1915), No. 114, pp. 715, 716).—The author contends that lime-sulphur solutions contain no soluble sulphite and that the use of the term "sulphite+sulphate" in the evaluation of such solutions is incorrect and should be replaced by the word "sulphate." Experimental data are submitted in support of this contention.

A new procedure for the evaluation, based on the following equations, is described:

 $\begin{array}{l} {\rm CaS_4 + 2AgNO_3 = Ag_2S + S_3 + Ca\ (NO_3)_2} \\ {\rm CaS_5 + 2AgNO_3 = Ag_2S + S_4 + Ca\ (NO_3)_2} \\ {\rm CaS_2O_3 + 2AgNO_3 = Ag_2S_2O_3 + Ca\ (NO_3)_2} \\ {\rm Ag_2S_2O_3 + H_2O = Ag_2S + H_2SO_4} \end{array}$

Briefly the procedure consists of diluting 10 cc. of the original solution to 100 cc. and designating this as solution A. To 50 cc. of tenth-normal silver nitrate diluted to 70 cc. 10 cc. of solution A is added, with constant agitation which facilitates the clumping of the precipitate and produces a clear supernatant liquid. After diluting the mixture to 100 cc. it is filtered by suction through a Gooch crucible into a dry suction flask. The precipitate is thoroughly

washed, dried for an hour and a half in a steam drying oven, and weighed as silver sulphid. The sulphuric acid and excess silver nitrate are then determined in an aliquot of the filtrate by adding from 20 to 30 cc. tenth-normal sodium chlorid and from 10 to 15 cc. tenth-normal sodium hydroxid, together with a few drops of phenolphthalein, and titrating with tenth-normal sulphuric acid to the neutral point. To the same solution a few drops of potassium chromate are added, and the excess of sodium chlorid titrated with tenth-normal silver nitrate.

For calculating the various forms of sulphur the following formulas are proposed:

Thiosulphate sulphur: $t=100\times 4(a-b).0.0016035=0.6414.(a-b)$;

Sulphid sulphur: $s=100\times2(25+c-d).0.0016035-t/2=0.3207(25+c-d)-t/2$; a=cc. tenth-normal NaOH; b=cc. tenth-normal H₂SO₄; c=cc. tenth-normal AgNO₃ used in titrating the excess of NaCl; d=cc. tenth-normal NaCl; t=thiosulphate sulphur; s=sulphid sulphur.

From the weight of silver sulphid (e) the polysulphid sulphur (p) is calculated as follows:

$$Ag_2S = 7.727.(s+t/2)$$
; p=100e-7.727.(s+t/2)

From these figures the amounts of tetra- and pentasulphid present can be calculated.

The results of several analyses carried out according to the proposed procedure are submitted.

Jellies and marmalades from citrus fruits, W. V. Cruess (California Sta. Circ. 146 (1916), pp. 8, figs. 2).—This circular discusses the preparation of jellies and marmalades from citrus fruits. Because of their richness in pectin the citrus fruits are especially suitable for this purpose, either to be used alone or blended with other fruits which are poor in pectin.

A thermometer and also a hydrometer test for determining the sugar concentration in the jelly sirup is described. Either of these tests is deemed far more reliable than the usual "sheeting" test.

Recipes for preparing the jellies and marmalades are included.

The distillation of apple cider in sugar-beet distilleries, E. SAILLARD (Monit. Sci., 5. ser., 6 (1916), I, No. 890, pp. 25-29).—This reports the progress of an investigation carried on with apple and beet products as possible sources of alcohol, which was ordered by the Minister of Agriculture in France.

The present situation of the question on the rôle of bacteria in voluntary decrease of acidity in wines, A. M. Krupenikov (Trudy Selsk. Khoz. Bakt. Lab., 5 (1914), pt. 2, pp. 195-220).—In the viticultural regions of Bessarabia, the Don, the Rhine, and the Moselle the grapes are not always fully ripe when used for making wine. Such wines contain large amounts of acid. Artificial means are used to diminish this acidity, such as the addition of water or calcium and potassium carbonates for the neutralization of the acids. This procedure, however, injures the wine.

To obviate this, experiments were made with various bacteria to determine their effect on reducing the acidity of the wine. The results showed that to decrease the acidity it is necessary to promote a very rapid fermentation with pure cultures of yeast by increasing the temperature of the cellar. The wine should be kept in contact as long as possible with the yeast, although the first transfusion should not be delayed so long as to injure the wine. The temperature after this operation should not be below 15° C. (59° F.). The residue should be thoroughly mixed so that the bacteria come in direct contact with the wine. The wine should be transfused into uncovered or only slightly covered barrels, allowing some of the residue to mix with the wine.

If it is desired to maintain the acidity of the wine the decrease can be checked by lowering the temperature or by fumigation.

It is indicated that this method of decreasing the acidity of wines by means of pure cultures of yeast bacteria is still in its infancy, and it is hoped that other bacteria will be found which can resist larger amounts of alcohol and acids than those used at present, viz, Saccharomyces apiculatus, S. ellipsoideus, and Bacillus gracilis.

A handbook for cane-sugar manufacturers and their chemists, G. L. Spencer (New York: John Wiley & Sons, Inc., 1916, 5. ed., rev. and enl., pp. XV+529, pl. 1, figs. 93).—This is the fifth edition, partly rewritten and enlarged, of this well-known handbook. The section devoted to manufacture has been greatly enlarged, and the processes in use in the manufacture of raw, plantation white, and refined sugars are described in detail. Methods for the analysis of sugar and the chemical control of the factory are given, together with procedures for the examination of various materials used in the process of manufacture. Many tables of value to sugar chemists and also of general interest are included.

Osage orange waste as a substitute for fustic dyewood, F. W. Kressmann (U. S. Dept. Agr. Yearbook 1915, pp. 201-204).—The dyestuff obtained from Osage orange waste has been found, by actual trial in the tannery, to be of value in dyeing leather, as it gives the same shades and depth of color as fustic.

Its application to cotton dyeing has not been fully demonstrated, although it is indicated that it could probably be used for the cheaper grades of twines and cords.

See also a previous note (E. S. R., 32, p. 613).

Ground-wood pulp, J. H. THICKENS and G. C. McNAUGHTON (U. S. Dept. Agr. Bul. 343 (1916), pp. 151, pls. 12, figs. 44).—This bulletin reports the results of tests on (1) the grinding of cooked and uncooked spruce and (2) substitutes for spruce in the manufacture of ground-wood pulp.

Complete data obtained from the tests are submitted in tabular form, and to some extent discussed. Samples of the paper made from the 25 different woods used, some of which were used in actual printing tests, are also submitted.

METEOROLOGY.

Agricultural meteorology, J. W. SMITH (U. S. Mo. Weather Rev., 44 (1916), No. 2, pp. 74, 75).—This article, which is an abstract of a paper presented at the Second Pan American Scientific Congress (E. S. R., 34, p. 308), defines agricultural meteorology, refers briefly to work along this line by the Weather Bureau and reports investigations by the author in the study of critical periods of farm crops in Ohio, especially by means of the curve chart and the dot chart as well as by calculation of the correlation coefficient. The crops included in the study were corn, potatoes, and winter wheat and the periods covered between 50 and 60 years.

It was found that the most important weather factor for both corn and potatoes is rainfall and the critical month July. Temperature was found to be the most important weather factor in the case of winter wheat and the critical month March. The critical rainfall for July in the case of corn is 3 in. It appears that July must be wet and moderately warm for the best crop of corn, but cool and moderately wet for the best growth of potatoes. The most important 10-day period for corn was found to be that immediately following blossoming when the weather must be wet and moderately cool. For potatoes the 10 days following blossoming must be cool and moderately wet. The most

critical 10-day period for corn is from August 1 to 10 and for potatoes from July 1 to 10. The dominant weather factor for winter wheat was found to be more difficult to determine than for the other crops. Contrary to the popular belief, it was found that there was no benefit to winter wheat from a snow covering or damage from lack of it. A snowfall in January appeared to be favorable, but, contrary to the usual opinion, snowfall in March was decidedly detrimental to winter wheat.

In the author's opinion "one of the first developments of agricultural meteorology should be to find the critical period in the growth of the various staple crops in different sections of the country."

Stories of the atmosphere, R. Nunn (U. S. Dept. Agr. Yearbook 1915, pp. 317-327, pl. 1, figs. 4).—It is stated that the object of this article is to suggest "titles and give glimpses into a few of the many stories that are available to those who desire to read them, either in books or in the air itself." It gives a very brief general account of the atmosphere and its circulation; points out some of the difficulties of studying the subject; calls attention to some interesting facts regarding atmospheric dust and moisture; sets forth the general plan and purpose of weather maps and what they show; and urges the importance of a more general study of the weather by reading and observation.

Dry fogs and their classification, G. G. Shenberg (Trudy. Selsk. Khoz. Met., No. 15 (1915), pp. 162, figs. 5).—Fog is defined as a haziness of the lower atmosphere decreasing its transparency. Fogs are divided into two classes, (1) damp fogs in which the decreased transparency of the atmosphere is due to minute drops of water or ice crystals and (2) dry fogs caused by scarcely perceptible particles of earth, dust, smoke, ashes, etc. Smoke fogs, ash fogs. dust fogs, optical fogs, and cosmic fogs are described in detail and a classification is proposed.

Monthly Weather Review (U. S. Mo. Weather Rev. 44 (1916), Nos. 1, pp. 1-60+XVII, pls. 11, figs. 6; 2, pp. 61-110, pls. 14, figs. 11).—In addition to weather forecasts, river and flood observations, and seismological reports for January and February, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during January and February, 1916; condensed climatological summaries; the usual climatological tables and charts; and a subject and author index for 1915, these numbers contain the following articles:

No. 1.—Solar Radiation Measurements at Lincoln, Nebr., 1911–1915, by H. H. Kimball; Solar Radiation Measurements at Madison, Wis., 1913–1915, by H. H. Kimball and E. R. Miller; Duration of Twilight (reprinted), by H. H. Kimball; Lunar Halo of July 24, 1861 (illus.), by W. B. Frew; Wind Velocity and Elevation (illus.), by W. J. Humphreys; Some Researches in the Far Eastern Seasonal Correlations (illus.), by T. Okada; Annual Hours of Fog, 1885–1915; an abstract of The Physician and the Weather Bureau (illus.), by F. A. Carpenter (E. S. R., 34, p. 509); and Alto-cumulus with Virgulus, by C. F. Talman.

No. 2.—Meteor Observations; Arequipa Pyrheliometry; Horizontal Rainbows on Lake Mendota (illus.), by C. Juday; Halos at Fort Worth, Tex., and Their Relation to the Subsequent Occurrence of Precipitation, by H. H. Martin; Origin and Maintenance of the Earth's Electric Charge, by W. F. G. Swann; Meteorology of the Moon (illus.), by W. H. Pickering; Agricultural Meteorology, by J. W. Smith (see p. 114); Breathing Wells and Pressure Changes; Alto-cumulus with Virgulus; Severe Ice Storm in Michigan; Relation Between Rainfall and Synoptic Winds, by H. H. Clayton; Long-range Forecast of the Winter Minimum Temperature for Hamada, Japan, by M.

Isida; Cirrus Directions at Melbourne and Storms Affecting Victoria, by E. T. Quayle; and Relation of Precipitation to Stream Flow in Montana (illus.), by R. F. Young.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 2 (1915), No. 13, pp. 404, pls. 2, flgs. 47).—This is a summary of climatological data of each State for the year 1915. The data are tabulated in detail and the principal weather conditions are summarized for each month and for the year.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), Nos. 1, pp. 236, pls. 2, figs. 6; 2, pp. 236, pls. 2, figs. 6).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for January and February, 1916, respectively.

Rainfall data of Berkeley, California, W. G. Reed (*Univ. Cal. Pubs., Engin.*, 1 (1915), No. 5, pp. 69-81).—Data for amount, frequency, and intensity of rainfall at Berkeley, Cal., are summarized for the period from 1887 to 1915.

Rainfall data of Berkeley, California, II, W. G. Reed and M. K. White (Univ. Cal. Pubs., Engin., 1 (1916), No. 6, pp. 83-116, pl. 1, fig. 1).—Supplementing the above report on rainfall observations, this paper summarizes incomplete data obtained from a recording rain gage maintained by the department of civil engineering of the university since 1911 for the purpose of studying the water supply of the university. The data are discussed with special reference to the frequency and intensity of the rainfall.

It is shown that the maximum intensity for the place and period of observations was at the rate of 3.5 in. per hour for 5 minutes and 0.5 in. per hour for 60 minutes. "A statistical and graphic study was made of all 12-hour periods for which intensity records are available. From this study the following indications have appeared: (1) When 0.8 in. falls in 12 hours there is a chance that the maximum rate for 1 hour exceeds 0.5 in.; (2) when 0.8 in. falls in 12 hours it is probable that 0.3 in. in 1 hour has been exceeded; this rate is half the maximum shown by the Grunsky curve and has been assumed as the lower limit of intensity of practical importance; (3) when 0.8 in. falls in 12 hours there is a chance that 0.15 in. in 5 minutes has been exceeded; this is the maximum given by the Grunsky curve for 5 minutes; (4) when 0.8 in. falls in 12 hours it is probable that 0.07 in. in 5 minutes has been exceeded; this has been assumed as the lower limit of intensity of practical importance; it is half the maximum given by the Grunsky curve."

California earthquakes during 1915, A. H. PALMER (Bul. Seismol. Soc. Amer., 6 (1916), No. 1, pp. 8-25, figs. 4).—A complete record is given.

Meteorological observations in Panama (Bol. Estad. Panama, No. 26 (1915), pp. 2-7).—Observations on pressure, temperature, humidity, precipitation, cloudiness, and winds during 1913 are summarized in tables.

Annual report of the weather bureau, 1914 (U. S. Dept. Int., Ann. Rpt. Weather Bur. [Philippine Islands], 1914, pts. 1 and 2, pp. 140).—Part 1 of this report contains brief statements regarding the stations, personnel, and work of the Philippine Weather Bureau. Part 2 gives tabular summaries of observations at the Central Observatory of Manila during 1914 on pressure, temperature, relative humidity, vapor pressure, clouds, and direction, velocity, and frequency of winds.

Is rainfall decreasing? (Agr. Gaz. N. S. Wales, 27 (1916), No. 4, p. 246).— The average rainfall of twelve towns in New South Wales by 10-year periods from 1856-1915 is tabulated and compared with the average for the whole period. The data are considered too limited to permit of definite conclusions, but attention is called to the fact "that the averages for the period 1886-1895 are almost invariably higher than those of any previous or succeeding period, and considerably above those of the average to date, while those for the period 1906-1915 are lower than any of the preceding ones."

SOILS-FERTILIZERS.

Soil survey of the Merced area, California, E. B. Watson et al. (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 70, pls. 4, fig. 1, map 1).—This survey, made in cooperation with the California Experiment Station and issued April 20, 1916, deals with the soils of an area of 614,400 acres, including nearly all of Merced County, California, and located nearly midway between the northern and southern ends of the San Joaquin Valley. The topography ranges from that of the foothills proper to flat. "The soils of the area fall naturally into four groups, (1) residual soils, (2) soils derived from old valley-filling material, (3) soils derived from recent alluvium and later valley-filling material, and (4) miscellaneous material." Forty-five soil types of 14 series are mapped of which the Madera series and the Fresno series are the most extensive.

Soil survey of Warren County, Indiana, E. J. Grimes and E. H. Stevens (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 39, fig. 1, map 1).—This survey, made in cooperation with the Indiana Department of Geology and issued April 12, 1916, deals with the soils of an area of 235,520 acres in western Indiana, the topography of which varies from level to undulating and broken, and in which "all the formerly water-logged areas of the prairie have been reclaimed by artificial drainage. . . .

"The soils of Warren County are derived largely from the unconsolidated deposits of the early Wisconsin glaciation." Including meadow, muck, gravel pits, and steep broken land, 15 soil types of 7 series are mapped, of which the Carrington and Miami silt loams and the Clyde silty clay loam cover, respectively, 37.4, 29.7, and 18.8 per cent of the area.

Soil survey of Muscatine County, Iowa, H. W. Hawker and H. W. Johnson (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 64, fig. 1, map 1).—This survey, made in cooperation with the Iowa Experiment Station and issued April 10, 1916, deals with the soils of an area of 276,480 acres in southeastern Iowa which lies in the glacial and loessial and river flood plain soil provinces. The topography is mainly level to gently rolling, with some hills and ridges.

The soils of the county are of glacial origin. Including marsh, muck, meadow, and river wash, 28 soil types of 9 series are mapped, of which the Muscatine, Memphis, and Buckner silt loams cover, respectively, 37.2, 19.7, and 7.5 per cent of the area.

Soil survey of Seward County, Nebraska, A. H. MEYER, E. H. SMIES, L. T. SKINNER, and W. A. ROCKIE (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 40, fig. 1, map 1).—This survey, made in cooperation with the Nebraska Soil Survey and issued April 25, 1916, deals with the soils of an area of 367,360 acres in southeastern Nebraska, the topography of which varies from flat to hilly and deeply dissected. "The streams are few, and there are sections in the county which are not tapped by any drainage way. Drainage is quite well developed, except on the broad divides in the western part of the county."

The soils are classified as upland, terrace, and first bottom soils. Eleven soil types of 7 series are mapped of which the Grundy silt loam covers 61.5 and the Wabash silt loam 12.3 per cent of the area.

Soil survey of Thurston County, Nebraska, A. H. Meyer, M. W. Beck, and W. A. Rockie (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 44, fig. 1, map 1).—This survey, made in cooperation with the Nebraska Soil Survey and issued April 22, 1916, deals with the soils of an area of 247,680 acres in northeastern Nebraska, the topography of which ranges from almost flat through rolling and steeply rolling to hilly and extremely dissected. As a whole, the county is said to be well drained.

The soils are upland terrace and first bottom soils. "There is considerable range in texture, from clay through silt loam, loam, sandy loam, and very fine sandy loam to sand." Including riverwash, 15 soil types of 9 series are mapped of which the Marshall and Wabash silt loams cover respectively 62.8 and 16.5 per cent of the area.

Soil survey of Florence County, South Carolina, J. H. AGEE, J. A. KERR, and W. E. McLendon (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 36, fig. 1, map 1).—This survey, issued April 17, 1916, deals with the soils of an area of 480,640 acres in east-central South Carolina lying wholly within the Coastal Plain province. The topography is level to very gently sloping.

The soils of the county are of old sedimentary and old and recent alluvial origin, "are predominantly sandy, and include coarse sands, coarse sandy loams, sands, sandy loams, fine sands, fine sandy loams, and very fine sandy loams. . . . The high and sloping sandy soils are well drained, while the low-lying soils and those having an impervious clay subsoil . . . have very poor or imperfect drainage." Including sandhill and swamp, 33 soil types of 10 series are mapped of which the Norfolk sandy loam and fine sandy loam, the Coxville sandy loam, and swamp soils cover, respectively, 14.6, 9.3, 8.5, and 13.3 per cent of the area.

Soil survey of McDowell and Wyoming counties, West Virginia, W. J. LATIMER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 32, fig. 1, map 1).—This survey, made in cooperation with the West Virginia Geological Survey and issued April 14, 1916, deals with the soils of an area of 669,440 acres comprising two counties in southern West Virginia which lie within the Allegheny Plateau and consist of a region thoroughly dissected by a series of widely branching streams which reach every part of their area. The surface is broken and mountainous and comprises a series of irregular ridges and deep, narrow valleys.

The soils of the area are of residual and old and recent alluvial origin. Including rough stony land, 12 soil types of 5 series are mapped, of which the Dekalb stony silt loam and silt loam covers 72.1 and 16.2 per cent of the area, respectively.

Analyses of Nova Scotian soils, L. C. Harlow (*Proc. and Trans. Nova Scotian Inst. Sci.*, 13 (1913-14), No. 4, pp. 332-346).—Analyses of 86 samples of Nova Scotian soils are reported and discussed. The results are taken to indicate (1) that the soils "have a good supply of potash, but that it is only slightly available, (2) that phosphoric acid in many soils is in small amounts, is about one-third available, and hence soon used, (3) that, while volatile matter is quite high, it is deficient in nitrogen, and (4) that lime is very deficient in many soils. . . . The great problem in Nova Scotia seems to be to increase and maintain the amount of available nitrogen,"

Relations between the total phosphoric acid content and the water- and citrate-soluble phosphoric acid in some soils of central Peru, A. HUTIN (Ann. Chim. Analyt., 20 (1915), No. 2, p. 31; abs. in Chem. Abs., 9 (1915), No. 13, p. 1816).—Analyses of six soils and their subsoils, selected from a large number

of analyses of soils from farms in central Peru, are reported, which show that while the total phosphoric acid content is higher in the soil than in the subsoil, the ratio of water- and citrate-soluble phosphoric acid to total phosphoric acid is very nearly the same for both soil and subsoil. In most cases about from 39 to 53 per cent of the total phosphoric acid of the soil was water- or citrate-soluble.

Soil investigations on the red beech litter experimental plats in the forest district of Philippsburg, K. Ganter (Forstw. Centbl., n. ser., 37 (1915), Nos. 7, pp. 312-335; 8-9, pp. 392-407, pls. 3; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1578, 1579).—Investigations on the physical and chemical properties of the soils of plats receiving the leaves and litter of beeches for a number of years are reported. Some of the plats were raked over annually, some once in five years, and some were left unraked. The unraked soil consisted of a layer of leaves and mold from 5 to 7 cm. (1.97 to 2.8 in.) thick, underlaid by 10 cm. of humus sand, and 70 cm. of gray sand. The soils raked every five years had a leaf and mold covering from 2 to 3 cm. thick, while the layer of humus sand was from 5 to 7 cm. in thickness.

It was found that the unraked soils showed the greatest total water content and the least evaporation, while the soils raked annually showed a medium water content and a high evaporation. Soils raked every five years had the smallest moisture content and an evaporation about equal to that of the unraked soils. The soils raked annually showed the greatest content and the soils raked every five years the smallest content of matter which could be washed out with water. The unraked soils were about equal in this respect to the soils raked every five years. These two types also showed the greatest porosity. The annually raked soils showed the highest, the soils raked every five years a medium, and the unraked soils the lowest, temperature. The unraked soils showed the greatest humus and nitrogen content and the greatest average increase in tree growth, followed in order by the soils raked every five years and the annually raked soils.

Contribution to the study of the soils of the east coast [of Madagascar], G. Carle and Gohier (Bul. Econ. Gouvt. Gén. Madagascar, 15 (1915), I, No. 1, pp. 35-41).—Chemical analyses of 49 samples of hill, plateau, and swamp soils and subsoils from the east coast of Madagascar are reported and discussed.

The hill soils are generally residual clays and are considered to be relatively deficient in phosphoric acid and to be generally unproductive. The plateau or alluvial soils are considered to be well supplied with nitrogen, phosphoric acid, and potash, but to be constantly deficient in lime. The swamp soils are well supplied with nitrogen, but are considered to be relatively deficient in phosphoric acid and lime. Proper drainage is said to be one of the most important factors in increasing the productiveness of the swamp soils.

The predominating minerals in Dutch East Indian soils, E. C. J. Mohr (Dept. Landb. Nijv. en Handel [Dutch East Indies], Meded. Lab. Agrogeol. en Grondonderz., No. 2 (1915), pp. 11).—This is a brief classified presentation of the mineralogy of these soils.

Soils and their treatment, W. J. Spafford (Jour. Dept. Agr. So. Aust., 19 (1915), No. 3, pp. 267-278).—This is an address before the Nantawarra Branch of the Agricultural Bureau of South Australia, in which the origin, physical, mechanical, and chemical properties of soils are briefly dealt with, special reference being made to the soils of the district.

The decomposition of clay marl, C. Cibielli (Bol. Min. Agr., Indus. e Com. [Rome], Ser. B, 14 (1915), I, No. 3-4, pp. 91, 92).—Tests of the effect of pro-

gressive heating of clay marl from 700 to 800° C. in an electric furnace led to the conclusions that the water of hydration is completely eliminated by heating to a temperature of 700°, and that the decomposition of carbonates and the elimination of carbon dioxid takes place rapidly at 800°. It was also found that the density tended to increase with progressive heating beyond 800°.

Improving acid soils, A. W. Blade (New Jersey Stas. Circ. 54 (1916), pp. 3-11, pls. 4).—This is a popular discussion of soil acidity and its causes, and its correction by the use of calcium carbonate, burned lime, hydrated lime, ground oyster shells, burned oyster-shell lime, unleached hardwood ashes, and basic slag. It is estimated that about four-fifths of the farm lands of New Jersey now under cultivation are acid to an extent that materially decreases crop yields.

Investigations of soil air on upland moors, A. Densch (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 33 (1915), Nos. 21, pp. 407-413; 22, pp. 423-428).—Investigations on the amount and composition of the soil gases of upland moors are reported. The soil samples were taken at depths of from 16 to 20 cm. (6.3 to 7.9 in.).

It was found that the absolute content of gas in upland moor soils, even with a high water content, was not less than that of mineral soils. The processes of oxidation and decomposition in cultivated upland moor soils in no case produced a large enough increase in carbon dioxid or decrease in oxygen content of the soil gas to influence plant growth unfavorably. Cultivated upland moor soil had almost identically the same oxygen and carbon dioxid contents as mineral soils. The composition of the gases of upland moor meadow soils corresponded approximately to that of lowland moor meadow soils.

Soluble nonprotein nitrogen of soil, R. S. POTTER and R. S. SNYDER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 2, pp. 61-64).—Analyses made at the Iowa Experiment Station of 5-gm. portions of silt loam soil, containing 0.3 per cent nitrogen, for alkali-soluble and soluble nonprotein nitrogen are reported.

"The general procedure followed was to determine the nitrogen in the alkali extract of soil with and without added material and the determination of nitrogen in the filtrate from the precipitate of the proteins in the alkali extract of soil with and without added material." The substances added "were chosen to represent classes of compounds which conceivably might be in soils." It was concluded that "if the results with the pure proteins be considered, it is probable that the alkali extract as a whole contains no definite group of compounds. From the results obtained by the precipitation of the alkali extract with trichloracetic acid it would seem that the soluble nonprotein fraction may contain most of the simpler nitrogenous compounds, and therefore its determination would give an index of the degree of decomposition of the organic matter in the soil."

The nature of humic acid, S. Odén (Ark. Kemi, Min. och Geol., 5 (1913–1915), No. 3-5, Art. 15, pp. 13; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 5, pp. 660, 661; Chem. Zentbl., 1915, I, No. 26, p. 1385).—Studies along the lines of work previously noted (E. S. R., 32, p. 813) with so-called black peat, dried sphagnum moss, and forest humus are reported, in which the electrical conductivity of a dilute ammonia solution, with and without the extract from the three types of organic matter, was observed.

Adsorption of ammonia was found to take place in the case of the extracts from all three samples of organic matter. At the same time considerable salt formation occurred in two cases where the dark humus was abundant, but not in the case of the dried sphagnum moss extract. These results are taken to indicate that one or more acids must exist in humus.

On the relative numbers of rhizopods and flagellates in the fauna of soils, C. A. Kofoid (Science, n. ser., 42 (1915), No. 1096, pp. 937-940, fig. 1).—This is a brief review of various investigations on the subject by others showing the differences in results obtained. A list of references to literature bearing on the subject is given.

Soil sampling for bacteriological analysis, H. A. Noves (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 5, pp. 239-249, pl. 1, fig. 1).—A method of sampling soil for bacteriological analysis, as described in the article previously noted (E. S. R., 34, p. 513), is presented, and comparative tests of this method with the soil auger method, the Iowa Station method (E. S. R., 27, p. 720), and the slice method are reported. These tests were conducted at the Indiana Experiment Station.

Fertilizer situation in the United States, D. F. Houston (U. S. Senate, 64. Cong., 1. Sess., Doc. 262 (1916), pp. 6).—This is a report from the Secretary of Agriculture in response to Senate Resolution 65, in which the fertilizer situation in the United States is briefly reviewed, with special reference to the shortage of potash and the high price of sulphuric acid needed for the manufacture of acid phosphate. The possible means of relieving the situation suggested are the production of potash from the alunite deposits of Utah and neighboring States and from the giant kelp beds of the Pacific coast, and the utilization of hydroelectric power for the production of soluble phosphates and of industrial wastes as nitrogenous fertilizers. Work of the Bureau of Soils on the utilization of kelp as a fertilizer and on electrical methods of producing soluble phosphates and synthetic nitrogen compounds is briefly referred to.

Mineral resources of the United States for 1914.—I, Mineral production of the United States in 1914, H. D. McCaskey (U. S. Geol. Survey, Mineral Resources of the United States Calendar Year 1914, pt. 1, pp. *1-*69, pl. 1, fig. 1).—This is a detailed summary of mineral production of the United States in 1914.

"The marketed production of phosphate rock in 1914 amounted to 2,734,043 long tons, valued at \$9,608,041, compared with 3,111,221 long tons, valued at \$11,796,231, in 1913; 2,973,332 long tons, valued at \$11,675,774, in 1912; 3,053,279 long tons, valued at \$11,900,693, in 1911; and 2,654,988 long tons, valued at \$10,917,000, in 1910. The quantity of phosphate rock reported as mined during 1914 was 2,649,174 long tons, against 3,152,208 long tons mined in 1913. The imports of crude phosphates, guano, kainit, manure salts, etc., for consumption were valued at \$9,921,439 in 1914, \$10,819,253 in 1913, and \$8,893,090 in 1912. The exports of phosphate rock in 1914 were 964,114 long tons, valued at \$6,771,652, against 1,366,508 long tons, valued at \$9,996,580, in 1913; and 1,206,520 long tons, valued at \$8,996,456, in 1912. There was no actual production of potash salts in the United States in 1914. The imports of potash salts (not including kainit and manure salts) for consumption were valued at \$8,743,973 in 1914, against \$10,805,720 in 1913."

Determination of the most convenient formula for the use of chemical fertilizers in agriculture, I. M. Concha (In *Primera Semana Social Agricola. Santiago de Chile: Universidad Católica de Santiago, 1914 pp. 3-14*).—The important factors involved in the determination of the fertilizer requirements of a soil are pointed out as the law of minimum, the composition of the soil, and the amounts of fertilizing constituents extracted from the soil by average crops. The value of field tests with crops is also noted.

Soil experiment fields.—A progress report, G. ROBERTS (Kentucky Sta. Bul. 199 (1916), pp. 43-93, figs. 12).—This is a progress report of studies at several

experimental farms in Kentucky, each of which is typical of a more or less extensive area of farming lands, on the fertilizer and manurial requirements of the soil and on crop rotations and adaptations.

Burnside Field, Pulaski County.—On a limestone soil, deficient in organic matter and nitrogen, growing corn, oats, clover, soy beans, and wheat, it was found "that no improvement was made in the absence of phosphates, and there was very little increase in yields due to potash. . . . On this soil acid phosphate is more effective, dollar for dollar, than rock phosphate. . . . The best yield of clover was made on the rock phosphate plat."

London Field, Laurel County.—On a moderately acid silt loam soil, with minimum potash content, growing a 4-year rotation of corn, cowpeas or soy beans, wheat, and clover, it was found that limestone and acid phosphate were highly beneficial, the most profitable treatment being a combination of the two. Potash used alone and with limestone and acid phosphate did not increase the yields, but gave profitable results when used only with acid phosphate. The results are taken to justify "the recommendation of the use of potash on the soils of this region when lime can not be used, especially on the more sandy soils."

Lexington Field, Fayette County.—Experiments on a slightly acid soil typical of the Trenton limestone region on which was practiced a rotation of corn, soy beans, wheat, and clover showed no consistent or decided effect from any of the fertilizing constituents (acid phosphate, potassium sulphate, or limestone) applied. It is considered safe to conclude that "the use of phosphates and potash is not necessary on the well-drained, highly phosphatic soils of the Trenton limestone formation when organic matter is maintained in quantities to furnish the necessary nitrogen for good crop yields."

Berea Field, Madison County.—Experiments on a strongly acid silt loam soil supporting a rotation of corn, soy beans, wheat, and clover, with cowpeas as a catch crop, led to the conclusion that "limestone and phosphates have shown decided results. Limestone is probably the first requirement of this soil and phosphate next. The best results were obtained by using both together."

Greenville Field, Muhlenberg County.—Experiments on a moderately acid silt loam soil, typical of the uplands of the Western Coal Field, on which two rotations were practiced, showed, with the rotation of corn, soy beans, wheat, and clover, with cowpeas as a catch crop and rye as a winter cover crop, "the need for the combination of limestone and phosphates in the improvement of these soils. . . . Potash has given good increases in some cases. . . . Wherever phosphates were used good yields of clover were obtained, whether any other material was used or not." With the tobacco, potatoes, and clover rotation no material increase was observed with any treatment which omitted phosphorus. Potash gave only slight increases. Limestone did not injure the potatoes and nitrogen was profitably used on tobacco and potatoes.

Russelville Field, Logan County.—Experiments with a slightly acid silt loam soil typical of the St. Louis limestone formation and supporting a rotation of corn, soy beans, wheat, clover, and timothy gave results which are taken to justify the conclusion "that limestone and phosphates may be used with profit on such soils, especially when used together. The effect of phosphates is especially apparent on wheat and clover. The effect of limestone is especially noticeable on the corn crop of 1915, as is also the case on the clover crop sown in 1915. Potash has produced considerable increases on the 1915 corn crop in some cases."

Lone Oak Field, McCracken County.—Experiments on a moderately acid silt loam soil typical of the uplands of the original wooded area of the Jackson Purchase and supporting a rotation of corn, soy beans, wheat, clover, and timothy with crimson clover or rye as a winter cover crop, gave inconclusive results. However, it is considered safe to recommend the use of limestone and phosphate on this soil, preferably together.

Mayfield Field, Graves County.—Experiments on a moderately acid yellow silt loam, typical of the untimbered land of the Purchase Region and on which a rotation of corn, oats, wheat, clover, and timothy was practiced, showed that "limestone and phosphates used together are giving decided increases. The effect of limestone and phosphates is very pronounced on the clover sown in the spring of 1915. In some cases potash has given good increases and in some it has not. . . . Nitrate of soda has given a profitable increase on one oats crop and on one wheat crop. . . . It is safe to say that nitrate of soda should not be used as a top-dressing on wheat in this region unless the ground is either fairly fertile or has been treated with phosphate."

Green manuring in the Central Provinces, R. G. Allan (Agr. Jour. India, 10 (1915), No. 4, pp. 380-394, pls. 2).—A review of experience with green manuring before wheat in the Central Provinces of India, using as green manures Sesbania, Crotalaria juncea, Cassia occidentalis, Psoralea corylifolia, Dolichos uniforus, and Vernonia cinerea, is given.

The results are taken to indicate that in similar climates "earliness of inversion is more important than quantity. The material should be in by the first week of August. It is desirable to sow with the first rains and to use either a quick crop like *C. juncea* or to collect weeds and apply. . . . Success is not likely unless at least 12 in., or better, 16 in., of rain is received after plowing in, while below 9 or 10 in. the results are not safe and the process is definitely inadvisable. The condition under which plowing is done must be kept in mind in judging the results and the effect of getting on the land at the wrong time allowed for, if necessary.

"When irrigation is available, either earlier sowing of the green crop is advisable, or, if the natural precipitation falls below the minmum of 9 in., the use of water to supplement the natural precipitation in rotting the green manure. Such irrigation must be applied before, not after, sowing the wheat.

"In areas where a rainfall of 12 in. after the first of August can not be relied on, some increased fertility can be gained by the growth of a legume and its use for fodder in the monsoon. In this case it is desirable to invert the stubble by mid-August so as to allow of consolidation by the later rains before sowing wheat. . . . In areas with a rainfall of less than 35 in. of ordinary monsoon distribution, green manuring for a wheat crop is practically out of the question."

Investigations relative to the use of nitrogenous plant foods, 1898–1912, J. G. Lipman and A. W. Blair (New Jersey Stas. Bul. 288 (1916), pp. 3-126, figs. 11).—This bulletin reports a continuation up until 1912 of the experiments described in a previous note (E. S. R., 21, p. 529) and summarizes the results of the 15 years' experiments.

It was found that the yield of dry matter and the percentage of nitrogen recovered in the crop were greatest with sodium nitrate, followed in order by ammonium sulphate and dried blood. "Of the various grades of manure used the solid and liquid stood highest in yield of dry matter and the solid, leached, stood higher than the solid, fresh. The highest average yield of dry matter and nitrogen from the main crops, third rotation, was where solid and liquid manure, fresh, was used in conjunction with the 10-gm. portion of nitrate of soda. The second highest yield was where solid and liquid manure, leached,

was used in conjunction with the 10-gm. portion of nitrate. In average yield of nitrogen for all series, the yield of the third rotation stands between the yields of the first and second rotations. The highest percentage of nitrogen recovered, third rotation, was with nitrate of soda alone. Next in order stood the cylinders on which solid and liquid manure, fresh, was used in conjunction with the 10 and 5-gm. portions of nitrate of soda, respectively. Slightly more nitrogen was recovered where the 10-gm. portion of nitrate was used than where the 5-gm. portion was used, and this is true whether the nitrate was used alone or in conjunction with manure. . . . Letting 100 represent the general average recovery for nitrate of soda, the recoveries for the other materials used were as follows: Ammonium sulphate 65.9; dried blood 60.7; solid manure, fresh, 36.4; solid and liquid manure, fresh, 49.1; solid manure, leached, 39.9. and solid and liquid manure, leached, 43.7.

"In general the percentage of nitrogen in the dry matter was slightly higher where manure and nitrogenous fertilizers were used together than where either was used alone. Likewise there was a tendency for it to be higher with the 10-gm. portion of nitrate than with the 5-gm. portion. The percentage of nitrogen in the dry matter was higher for the third rotation than for either the first or second.

"Lime in the form of carbonate had a pronounced beneficial effect upon the yields in general. The improvement was greatest where it was used in conjunction with ammonium sulphate.... Where manure was used with ammonium sulphate, the former counteracted, in a measure, the acid tendency of the latter. Lime and green manure crops, in conjunction with manure and the nitrogenous fertilizers, gave the largest yields of dry matter and nitrogen....

"Notwithstanding the fair applications of manure and nitrogenous fertilizers, the cylinder soils have gradually lost in content of total nitrogen, though the loss has been greater on some than on others. Loss of nitrogen was greater with solid manure, fresh, than with solid and liquid, fresh; it was greater with the solid and liquid, leached, than with the solid, leached. The loss was almost as great with 5 gm. of nitrate of soda as with 10 gm. Generally speaking, the loss was greater where manure and nitrogenous fertilizers were used together than where either was used alone; where ammonium sulphate and dried blood were used in equivalent amounts, the loss was greater with the former....

"Where the nitrogenous fertilizers were used alone there was but little recovery of nitrogen through the residual crop. Where nitrate of soda and dried blood were used in conjunction with green manures, there was a fair recovery of residual nitrogen, but the nitrogen thus recovered must not all be credited to the fertilizing materials. Where manure was used alone, or in conjunction with nitrogenous fertilizers, there was, without exception, some recovery of residual nitrogen. . . .

"It is concluded from the data here presented that the destruction of nitrates—that is, denitrification, does not take place to any great extent in general farming, under average field conditions, even when liberal amounts of barnyard manure are used.

"It is not possible to maintain the nitrogen supply of the cultivated soils by the use of commercial nitrogenous materials alone when used in the ordinary amounts. Even with liberal applications of manure and nitrogenous fertilizers covering a period of fifteen years, the nitrogen content of soil under constant cultivation was not maintained. The loss of nitrogen is attributed largely to loss through leaching," Cylinder experiments relative to the utilization and accumulation of nitrogen, J. G. Lipman and A. W. Blair (New Jersey Stas. Bul. 289 (1916), pp. 3-88, figs. 18).—Seven years' experiments with a 4-year rotation of corn, potatoes, oats, and rye on two types of sand, fine sand, two types of sandy loam, two types of loam, and gravelly loam soils are reported, the purpose of which was to determine the relative value of the nitrogen of sodium nitrate, green manure crops, and stable manure. The sodium nitrate was used at the rate of 160 lbs. per acre, green manure crops consisting of crimson clover, vetch, soy beans, and cowpeas were seeded after each main crop, and stable manure was used at the rate of 15 tons per acre applied once in two years.

"The fertilizer treatment provides for two cylinders each without any fertilizer, two with minerals only, two with minerals and nitrate of soda, two with minerals and green manure, and two with minerals and stable manure, for each type of soil. All soils received a treatment of ground limestone when the experiment was begun, and similar applications at the end of each 5-year period."

Determinations of soil nitrogen after 5 years showed that "there has been a gradual depletion of the nitrogen content of the soil for six out of the eight types, even where nitrogenous fertilizers have been applied and where green manure crops have been grown. The soils from the check cylinders show the lowest percentage of nitrogen. The soils from the cylinders which receive minerals only and those which receive minerals and nitrate of soda show essentially the same percentage of nitrogen. The soils from the cylinders which receive minerals and green manure, and from those which receive minerals and stable manure, likewise show practically the same percentage of nitrogen, and this amount is about 0.01 per cent higher than in those cylinders where minerals only and minerals and nitrate of soda are used. It thus appears that the green manure crops have been quite as effective in maintaining the nitrogen supply of the soil as stable manure at the rate of 15 tons per acreapplied once in two years. . . .

"The unfertilized cylinders gave the lowest yield of dry matter and nitrogen, and those that received minerals only the next highest. The cylinders that received minerals and nitrate of soda gave a higher yield of dry matter and nitrogen than those that received minerals only. . . . The highest yields of nitrogen and dry matter were from cylinders where green manure crops have been grown, and the next highest from those where stable manure has been used."

Calculation of the percentages of nitrogen recovered from sodium nitrate and stable manure showed that "in most cases this recovery was low for both the nitrate and the manure. The average recovery for nitrate for the 7 years was 39.59 per cent and for the manure it was 11.04 per cent. . . .

"Of the different types of soil the Norfolk sand gave the lowest yield of dry matter and nitrogen and the Quinton sandy loam the highest yield. The Penn loam stands next to the Quinton sandy loam. . . . On the Norfolk sand and Elsinboro fine sand the nitrogen supply of the soil has just been maintained by the use of green manure and stable manure. On the other six types the nitrogen supply is now less than when the experiment was begun, even where green manure and stable manure have been used.

"Since the yields with the green manure have, on the average, been greater than with stable manure, and since the nitrogen supply of the soil has been maintained on a level with that on the stable manure cylinders, it seems fair to conclude that the green manure crops have furnished at least as much nitrogen each year as the stable manure, and . . . that a small or moderate green

manure crop (none of the crops were large) will supply 70 to 80 lbs. of nitrogen per acre, which is equivalent to about 450 to 520 lbs. of nitrate of soda."

Lime nitrogen fertilizer experiments in 1915, AHR (*Mitt. Deut. Landwo. Gesell.*, 30 (1915), No. 48, pp. 732–737).—Sixteen series of experiments, comparing lime nitrogen with ammonium and nitrate fertilizers when added as a top-dressing to rye and wheat and before seeding to oats, potatoes, and beets in amounts equivalent to 15, 15.5, 20, 22.5, 30, 45, and 60 kg. of nitrogen per hectare (13.35, 13.8, 17.8, 20.025, 26.7, 40.05, and 53.4 lbs. per acre), are reported.

It was found that with few exceptions the nitrogen additions favorably influenced the yield. In fourteen of the series ammonium sulphate had in general a considerably more favorable influence than lime nitrogen. Lime nitrogen when added before seeding was, however, slightly more favorable to beets and potatoes than was ammonium sulphate. In one series lime nitrogen when added before seeding gave as good results as ammonium nitrate and better results than any of the other nitrate forms used. The results with lime nitrogen as a top-dressing for potatoes were very poor, and lime nitrogen was much less favorable for beets than was ammonium nitrate. The results as a whole are taken to indicate that the action of nitrogenous fertilizers is influenced by local environmental factors, especially soil and climatic conditions and kind of crop grown.

It was found in further experiments that mixing lime nitrogen with pulverized bog iron ore increased the fertilizing action of the lime ntrogen for winter wheat and rye, but not for oats. The results of experiments with a mixture of lime nitrogen with superphosphate were inconclusive.

Experiment on the effectiveness of some new ammonium salts as compared with sodium nitrate, ammonium sulphate, lime nitrogen, liquid manure nitrogen, and some organic nitrogenous fertilizers, P. WAGNER (Mitt. Deut. Landw. Gesell., 30 (1915), No. 47, pp. 714-720, figs. 3).—Pot culture experiments on loam and sand soils with sodium nitrate, ammonium sulphate, sodium-ammonium sulphate, ammonium carbonate, ammonium chlorid, blood meal, liquid manure, castor-bean meal, powdered and granulated lime nitrogen, a wool fertilizer, and an organic fertilizer, when added in amounts equivalent to 0.5, 1, and 1.5 gm. per 20 kg. of soil to summer rye, summer wheat, and white mustard, are reported.

Considering the effectiveness of ammonium sulphate as 100, with reference to both yield and nitrogen utilization, the effectiveness of sodium-ammonium sulphate was 93 for both, of ammonium carbonate 102 for yield and 103 for nitrogen utilization, of ammonium chlorid 104 and 98, of lime nitrogen 104 and 105, of blood meal 98 and 100, of liquid manure 91 and 94, of castor-bean meal 72 and 63, of the organic fertilizer 49 and 48, and of wool fertilizer 21 and 25. No difference was observed in the results obtained with lime nitrogen of different degrees of fineness.

Potash supplies during the war (Bd. Agr. and Fisheries [London], Spec. Leaflet 42 (1915), pp. 4).—This leaflet points out briefly the importance of the preservation and use of potash in barnyard manure, crop residues, seaweed, and wood ashes during the coming year, and discusses the liberation of soil potash by liming and applying sodium salts. Suggestions for the treatment of particular crops are given.

Potash: Review of the present position, A. Bruce (Trop. Agr. [Ceylon], 45 (1915), No. 1, pp. 4-14).—This is a review of the present potash situation, with special reference to its effect on tropical agriculture. A table showing the ash and potash contents of various tropical plants is included.

The composition of wood and plant ash, R. A. Beery (Jour. Bd. Agr. [London], 22 (1915), No. 8, pp. 766-768).—Analyses of representative samples of the ash of certain forest and plant products and of flue dust, made at the West of Scotland Agricultural College to determine their potash and phosphate contents, are reported. The following table summarizes the analyses:

Ash analyses of miscellaneous materials.

Kind of ash.	Total potash (K ₃ O).	Percentage of total potash sol- uble in water.	Phosphate
Bracken Spruce Mixed forest produce. Hardwood, engine fire Softwood, forest fire Hardwood, largely oak trimmings Flue dust from blast furnaces, No. 1. Flue dust from blast furnaces, No. 2.	10. 44 11. 79 3. 53 3. 75	Per cent. 51.9 68.9 47.9 64.8 55.4 77.9 56.8 67.2	Per cent. 7. 35 15. 30 3. 36 10. 95 11. 41 2. 40 (1) (1)

¹ Not ascertained.

Composition of bat guano from Uruguay, J. Schroeder (Rev. Assoc. Rural Uruguay, 44 (1915), No. 9, pp. 529-531).—Analyses of two samples of this guano are reported, showing total nitrogen 5.59 and 6.93 per cent, total phosphoric acid 7.45 and 5.54 per cent, and potash 3.14 and 2.78 per cent. While this guano compares favorably in composition with guanos from North America and South Africa, it is said to be too limited in amount to be commercially profitable.

Fertilizing value of sugar beet crowns and leaves (Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 4 (1915), pp. 90–100; abs. in Jour. Bd. Agr. [London], 22 (1915), No. 8, pp. 759, 760).—Analyses of sugar beet crowns and leaves are reported, together with the results of field tests to determine the effect of plowing under the beet crowns and leaves on oats and potato crops following beets. The analyses showed nitrogen varying from 2.24 to 2.37 per cent, phosphoric acid from 0.73 to 0.78 per cent, and potash from 2.88 to 3.23 per cent.

At the Lauchstädt experiment station it was found that plowing under the beet leaves and crowns was accompanied by a marked increase in the oat and potato crops and in the percentage of the larger sized potatoes. The increase in the potato crop was greater where the beet crowns and leaves were used without additional fertilizer. Where leaves and crowns were tested separately the largest increase in potato crop was obtained with the crowns. The potato crop produced with leaves alone was slightly greater than that produced with leaves and crowns together, but was much less than that produced by leaves and crowns and ammonium phosphate or by ammonium phosphate alone.

Inspection of commercial fertilizers, 1915, F. B. Mumford and P. F. Trow-Bridge (Missouri Sta. Bul. 139 (1916), pp. 58, figs. 2).—This bulletin contains the results of actual and guarantied analyses and estimated valuations of 494 samples of fertilizers and fertilizing materials collected for inspection in Missouri during 1915, together with a list of brands registered in the State during 1915 and a statement of the substance of the Missouri fertilizer law. It was found that of the official samples analyzed 35.5 per cent gave a total value averaging \$1.28 a ton below guaranty. Analyses and valuations of commercial fertilizers and ground bone. Analyses of agricultural lime, C. S. Cathcart et al. (New Jersey Stas. Bul. 287 (1915), pp. 3-68).—This bulletin contains the results of actual and guarantied analyses and valuations of over 1,000 samples of fertilizers and fertilizing materials, including analyses of 43 samples of ground bone, 45 samples of lime, and 32 samples of such sundry materials as tobacco stem ash, boneblack, prepared humus, tobacco stems, street sweepings, incinerator ashes, seaweed, flue dust, wood ashes, burned peat, cacao shells, hardwood ashes, humus, sludge, fish meal, and sewage residue, collected for inspection in New Jersey during 1915 in continuation of work noted in Bulletin 285 (E. S. R., 34, p. 625.)

AGRICULTURAL BOTANY.

Plant life, C. A. Hall (London: A. & C. Black, 1915, pp. XI+380, pls. 74, figs. 80).—This book, while popular as regards content and style, and intended primarily for nature lovers and amateur botanists, deals with most of the main divisions and topics usually considered in connection with a more formal and scientific study of plant life, including a chapter on fossil plants.

Mass mutation in Enothera pratincola, H. H. BARTLETT (Bot. Gaz., 60 (1915), No. 6, pp. 425-456, figs. 15).—This article, while considered to be of a preliminary character as regards many genetic relationships between the mutations and the parent species, reports a continuation of studies previously noted (E. S. R., 33, pp. 221, 524). It deals with mutations of Œ. pratincola, which gives rise, in successive generations, to mutations belonging to several distinct types. The most conspicuous of these, when young, is Œ. pratincola nummularia, originating in every generation from seven of the eight independent strains which have been studied. The eighth strain exhibits the phenomenon which has been called by the author "mutation en masse," and has been designated as Lexington E. This differs from all the other strains of Œ. pratincola in that it gives rise to a characteristic group of four mutations, that these occur in such large numbers as to justify the use of the term mass mutation, and that it does not give rise to the mutant Œ. nummularia and certain other mutations produced by strains which do not show mass mutation.

Enothera gigas nanella, a Mendelian mutant, H. Devries (Bot. Gaz., 60 (1915), No. 5, pp. 337-345).—The author gives an account of studies as a result of which he states that Œ. gigas produces dwarfs (about 1 to 2 per cent) and mutant hybrids of normal stature, which, after self-fertilization, give from 15 to 18 per cent (theoretically 25 per cent) of dwarfs. These mutant hybrids mendelize after self-fertilization, yielding about 18 per cent of dwarfs, 25 per cent of normal specimens of tall stature, and 57 per cent of hybrids of the same type. The latter gave among their progeny about 21 per cent of dwarfs. The mutant hybrids, fertilized by Œ. gigas nanella, yield from 30 to 43 per cent (theoretically 50 per cent) of dwarfs.

In artificial crosses with E. gigas the dwarfs follow Mendel's law. The production of dwarfs from E. gigas by means of mutation is, therefore, considered as requiring the copulation of two gametes, both of which are potentially mutated into dwarfs. The mutant hybrids, then, it is thought, must be the result of the fertilization of a mutated gamete by a normal one. They are correspondingly less rare than the dwarfs themselves. In view of the fact that dwarfs of E. lamarckiana do not follow the law of Mendel, either in their origin by mutation or in artificial crosses with the parent species, these conclusions are thought to show a new differential character between E. gigas and its parent species.

Three types of commercial vanilla in Tahiti, Costantin and Bois (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 8, pp. 196-202).—Discussing three types of vanilla in Tahiti, the authors state that the type called Mexican vanilla is V. planifolia, that the type called Tahitan vanilla is closely related thereto, but that the type which has been provisionally called V. tiarei, and which is thought to have appeared there five or six years ago from an unknown source, may be a variation or a hybrid. It is said to possess qualities of commercial value.

Quichua names of sweet potatoes, O. F. Cook (Jour. Wash. Acad. Sci., 6 (1916), No. 4, pp. 86-90).—The author gives some results of studies carried out by himself as a member of the Yale Peruvian Expedition, conducted by Prof. H. Bingham in cooperation with the National Geographic Society and the U. S. Department of Agriculture.

It is stated that the Quichas, who live on the eastern slopes of the Andes, use and have used apparently from antiquity the names "apichu" for the sweet varieties of *Ipomæa batatas* and "cumara" for the starchy kinds, the inclusive term "camote" being used for both kinds by those who speak Spanish. Both these varieties are represented by local strains having local names, a number of which are given. Wild sweet potatoes are also said to be common in the valleys of the interior.

It is stated that, while among all the native names used in other parts of America there appears to be no definite resemblance to the Quichua words "apichu" and "cumara," the number and variety of such names testify to the American origin of the sweet potato, or at least to its wide distribution in prehistoric times. The name "cumara," or "kumara," is also used for the sweet potato in Polynesia. This fact is regarded as more than a mere coincidence.

Physico-chemical studies in botany.—I, Germination, Helene Nothmann-Zuckerkandl (Internat. Ztschr. Phys. Chem. Biol., 2 (1915), No. 2-3, pp. 94-106).—This is a review of the results and conclusions published by previous investigators on germination.

The germination, under aseptic conditions, of Zea mays in the presence of some quinonoids, D. Roudsky (Compt. Rend. Soc. Biol. [Paris], 77 (1914), No. 20, pp. 30–33, fig. 1).—Describing the behavior of maize seedlings grown by placing sterilized seeds on cotton in test tubes, the author notes that, while in case of the control tubes containing water only the roots penetrated the liquid freely and attained considerable development, in tubes containing a dilute solution of an azin, a diamidoacridin, or one of two oxazins, the roots failed to descend into the solution, a portion of the rootlet showing also a certain coloration extending to the growing part. The lowering of the liquid surface of the solution due to evaporation was followed by renewed growth of the rootlet, in some cases carrying its point into the liquid, this fact suggesting a degree of adaptation to a medium which at first appeared to inhibit growth.

Light and growth, II, A. H. Blaauw (Ztschr. Bot., 7 (1915), No. 8, pp. 465-532, figs. 10).—The author has followed up his work previously reported (E. S. R., 34, p. 223) with studies on plantlets of Helianthus globosus as regards rate of growth and response to illumination of various intensities and durations.

It is held that in multicellular organisms a characteristic growth reaction is produced which is due to physico-chemical change. Phototropism is a secondary phenomenon of the growth reaction to light which results when the plant is subjected to unequal illumination on different sides. Plant cells are not stimulated because of obliquity of light or of unequal intensity thereof on different sides. There is no perception of light or of differences of illumination, but light produces alterations in growth rate which may quickly manifest themselves through a striking response.

The stimulation of protoplasmic streaming by rays of different sorts, Helene Nothmann-Zuckerkandl (Ber. Deut. Bot. Gesell., 33 (1915), No. 6, pp. 301-313, figs. 2).—It has been found that visible ultraviolet and ultra-red rays cause in the plasma of leaf cells of Elodea streaming movements, the activity of which increases with the wave length. While the establishment of a temperature gradient by local warming in case of a single leaf caused streaming movements, the warming of the whole shoot by immersion in water had no influence in this connection.

The pigments of fruits in relation to some genetic experiments on Capsicum annuum, W. R. G. Atkins and G. O. Shebrard (Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1915), No. 25, pp. 328-335).—Presenting results of a preliminary nature from a study of the genetics of fruits of C. annuum, the authors state that in these fruits red is dominant to yellow and appears to be a simple dominant to chocolate and orange. Differences in the shades of green in unripe fruits are ascribed to variations in the numbers of chromatophores contained in each cell. The colors of ripe fruits are due to red, chocolate, orange, and yellow plastid pigments. Red and chocolate have not been shown to be due to a mixture of pigments. Some red fruits contain water-soluble yellow pigment in small quantities.

Red and chocolate pigments, when pure, are oily liquids which have not been obtained in a crystalline condition. This property, with their ready solubility in cold alcohol and petroleum ether, distinguishes them from lycopin, carotin, and xanthophyll, the solutions becoming colorless when allowed to evaporate in sunlight. Carotin is moderately soluble in cold pyridin and yields crystals from this solvent similar to those from ethereal solution.

Peroxidase in Capsicum fruits diminishes as they ripen and bears apparently no simple relation to variety. The enzym is frequently present only in the epidermis, while the deeper tissues may contain an inhibitor with a strong reducing action.

The origin and transformations of anthocyanin products, F. Moreau (Bul. Soc. Bot. France, 61 (1914), No. 7-9, pp. 390-405).—Referring to the view expressed in an earlier communication (E. S. R., 33, p. 523), that mitochondria take part in the formation of anthocyanin both in flowers and in vegetative organs, the author states that his later studies appear to indicate that the conclusions formerly announced should be considered as subject to modification by the results of investigation of more abundant material under more favorable conditions.

It is now held that anthocyanin in floral or vegetative parts may be of mitochondrial origin. On the other hand, in numerous cases the anthocyanin appears not to have been formed wholly in the chondriosomes or the anthocyanin corpuscles, but to have been preceded by the formation of colorless products which become colored more or less slowly. The colored anthocyanin products may themselves be transformed into colorless products. It is considered proper, therefore, to rank along with the red, violet, and blue pigments now designated as anthocyanins the colorless compounds which are inseparable from them for purposes of study and which are always found in the cells as earlier or later products, being closely related to them as regards chemical composition and as having in common with them a mitochondrial origin.

Oxidases and their inhibitors in plant tissues.—IV, The flowers of Iris, W. R. G. Atkins (Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1915), No. 24, pp. 317-327).—In this work the list of Iris flowers previously employed for a study of peroxidase reactions (E. S. R., 31, p. 626) has been extended greatly and much of the previous work has been repeated with a view to finding out how

far the activities of oxidizing enzyms depend upon the age of the flower and other factors, such as illumination.

It is stated that peroxidase reactions of certain species and varieties of Iris are similar, though the distribution and quantity of anthocyanin may be very different. Peroxidase reactions are well marked in the Xiphion group, variable as regards distribution in the Apogon group, and absent in the Pogoniris group. Active peroxidase increases more or less in Iris flowers kept in darkness, and the production of organic peroxid was recorded in one case. Owing presumably to complications introduced by inhibitors, it is impossible in Iris to correlate the distribution of peroxidase and anthocyanin, the latter frequently appearing in the absence of the former in an active state.

The formative starches of green leaves and their utilization, F. W. Neger (Naturwissenschaften, 3 (1915), No. 31, pp. 407, 408).—Discussing the carbohydrate content of green leaves, the time at which it is greatest, and the possibility of its more economical utilization, the author notes some findings reported by former investigators or obtained by himself.

Observations on the starch content of several plants show that in these cases the maximum, while it may occur at different hours, generally falls in the afternoon or evening. The starch content of leaves and its transfer appear in most cases to be diminished under very high temperatures. The practice of gathering vegetables late in the afternoon is most profitable only when the accumulation of carbohydrates during this period is not too largely neutralized by its transfer to the stems before its sale and utilization the next day.

In regard to the removal of the leaves, which is suggested, starches tend to change into sugars, due to the presence of a ferment in the leaves, the activity of which seems to bear some rather intimate relation to respiration. It is suspended in irrespirable gases, but is resumed after removal therefrom if they are of a nonpoisonous character. In case of leathery leaves or, in particular, those of evergreens, the stores of carbohydrates are often larger, being the net accumulations of several days. The mobility of starch is much less in evergreen than in deciduous leaves. It is stated that the foliage of conifers contains, particularly in autumn and spring, large quantities of starch in a stable condition.

The starch economy of green plants, F. W. NEGER (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 8-9, pp. 370-380).—This is a more detailed account of the facts summarized in the article noted above.

Starch formation in underground portions of herbaceous plants, J. D'ARBAU-MONT (Bul. Soc. Bot. France, 61 (1914), No. 5-6, pp. 347-351).—The author has followed the work of Guilliermond (E. S. R., 28, p. 524) in the study of starch formation as related to leucoplasts. He states that besides the concentric development of the starch grain there may be noted two other phases, namely, a peripheral phase developing centripetally and one developing both centripetally and centrifugally at the same time from the periphery and the center, respectively. These and related phenomena are discussed as noted in different plants.

Humus as a source of carbon for green plants, M. Molliard (Rev. Gén. Bot., 27 (1915), No. 313, pp. 1-9).—The author gives an account of experimentation from which he concludes that humus can not be considered a direct source of carbon for green plants to any appreciable extent.

The rôle of the ash constituents in living plants, I, M. A. Egorov (Zhur. Opytn. Agron., 16 (1915), No. 4, pp. 270-280).—In a preliminary account of the relation between ash constituents and maturation it is stated that oats remain green after being desexed. It is thought that the direct cause of maturation in the Gramineæ, so far as that is manifested in the yellowing of the plant, is the

transfer of magnesium in considerable quantity to the grains, where it is fixed.

The root nodules of Ceanothus americanus, W. B. Bottomley (Ann. Bot. [Londom], 29 (1915), No. 116, pp. 605-610, pl. 1).—Giving an account of investigations on C. americanus, the author states that the root nodules of this plant are modified lateral roots, perennial in character and increasing each year by the formation of endogenous outgrowths or branches structurally similar to the branch from which they primarily arise. Each primary nodule or branch develops four zones designated respectively as meristematic (apical), infection, bacterial, and basal. The younger bacterial cells contain rod-shaped organisms, the older ones spherical bodies, the latter being the bacteroid condition of the active nitrogen-fixing rod-shaped bacillus. The bacteria, when isolated and grown in pure culture, are able to fix atmospheric nitrogen and are considered to belong to the Bacillus radicicola group.

The aerating system of Vicia faba, C. Hunter (Ann. Bot. [London], 29 (1915), No. 116, pp. 627-634, figs. 6).—A description is given of the aerating system demonstrated for V. faba. It is thought that the division of the air cavities in young internodes facilitates gas interchange in the active region of the growing point. It is suggested that the production of lysigenic cortical air cavities in old internodes is a device to assist in respiration by the cortical cells of the old root. The development of the intercellular space system of the root tip is thought to show the great importance of the aerating system in the most active regions of cell development.

On the coagulation of Hevea latex and a new method of coagulation, B. J. EATON and J. GRANTHAM (Agr. Bul. Fed. Malay States, 4 (1915), No. 2, pp. 26-30).—Reporting work designed to test the hypothesis of Whitby (E. S. R., 29, p. 149) that the spontaneous coagulation of Hevea latex is brought about by a coagulating enzym, the author claims that these experiments indicate that this natural coagulation of the latex of H. brasiliensis is due to certain bacteria which infect the latex after collection. There are two types of organism, one (favored by aerobic conditions) which tends to inhibit coagulation and produces an alkaline slime in the presence of air, and the other (favored by anaerobic conditions) which effects coagulation of the latex. The coagulation of the latex under anaerobic conditions is not constant, owing, it is thought, to a variation in the constitution of the latex. By the addition of various sugars, coagulation under both aerobic and anaerobic conditions always occurs. This is thought to be explainable on the supposition that a medium is formed more favorable for the organisms which produce congulation and less favorable to those producing putrefactive changes.

The assimilative capability of witches' brooms on cherry, E. Heinricher (Ber. Deut. Bot. Gesell., 33 (1915), No. 5, pp. 245-253, figs. 2).—It is stated that, in experiments described, considerable assimilation of carbon dioxid was accomplished by the foliage of witches' brooms in case of cherry.

Dwarfing effect of trees upon neighboring plants, J. Y. Bergen (Bot. Gaz., 60 (1915), No. 6, pp. 491, 492).—Discussing the factors generally mentioned in connection with the deficient growth of plants in the shade of trees, namely, shading, abstraction of water and of salts, and the possible excretion of injurious substances by the trees, the author records observations made during the very rainy summer of 1915, in Cambridge, Mass., on some growing plants shaded by a belt of deciduous trees.

It is stated, regarding Aster novæ-angliæ, Asclepias tuberosa, and Helianthus grosse-serratus, that, while none of these flourished as well as did other individuals growing in open ground, all were perhaps twice as tall as during an

ordinary season and were much more robust than usual. A specimen of Chelone glabra grew luxuriantly and flowered freely, though for some years it had barely kept alive. On the other hand, the rather xerophytic Sedum telephioides and Hedera helix showed no better growth than usual, and some other plants, as Saponaria officinalis and Oxalis corniculata, showed little increase over their usual size. It is thought that the differences noted were due to increased water supply, and that many plants of agricultural importance may be as sensitive to the effects of diminished water supply as the Aster, Asclepias, and Helianthus previously mentioned.

Radium and plant growth (Gard. Chron., 3. ser., 58 (1915), No. 1501, p. 209).—In comments on the results of a number of experiments said to have been carried out by M. H. F. Sutton, it is stated that in no case was it apparent that any of the radium preparations had a beneficial effect on the growth of the crops. In not a few instances there were definite indications that the preparations had exercised an adverse influence on the plants.

Bibliography on the effect of sulphur dioxid on vegetation and animal life (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 503-520).—This bibliography, which is said to have been prepared by the chemists' club library of the Selby Smelter Commission, lists nearly 100 articles upon the biological effects of sulphur dioxid, giving notes or brief abstracts of most of the articles mentioned.

Disappearance of sulphur dioxid from dilute mixtures of sulphur dioxid with air, G. C. Bartells, Jr. (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 308-323, pls. 2).—These investigations were carried on to test certain observations made in the field fumigation experiments previously noted (E. S. R., 35, p. 28).

It is stated that the disappearance of sulphur dioxid from a mixture thereof with air, when introduced into a carboy containing green vegetation, was found to be due in great part to absorption of sulphur dioxid by the plant, but in some degree also to the oxidation of the sulphur dioxid in an excess of moist air and to absorption by the surface of the glass. Experimentation showed also that when a mixture of sulphur dioxid and dry air was left in a glass container, there was a disappearance of the sulphur dioxid to the extent of about 10 per cent in 30 hours. The disappearance was greater when the air showed a relative humidity of 50 per cent than it was in dry air, and much greater at a humidity of 100 per cent. When a mixture of sulphur dioxid and air was exposed to the action of direct sunlight, a gradual disappearance of the sulphur dioxid took place. This was greatest when the temperature was highest, which fact is considered to preclude the view of its solution by water. In all cases both oxidation and absorption took place to an extent which was greater in a moist than in a dry atmosphere.

Defects in the investigation of smoke injury, S. Eicke (Ztschr. Pflanzen-krank., 25 (1915), No. 1, pp. 45-59).—Discussing the methods, results, and present state of study of the relations between soil, plant, and smoke, also between smoke and the aerial portions of plants, the author calls attention to some of the gaps in our present knowledge in this connection.

Tests of various brands of litmus for bacteriological work, Christie J. Mason (Connecticut Storrs Sta. Bul. 83 (1915), pp. 126. 127).—The author gives a report on an investigation of different brands of litmus to determine their adaptability for bacteriological purposes, basing her conclusions on the numbers of bacteria which developed in litmus-lactose-gelatin plates prepared for testing milk or its products. Of the four brands of litmus tested, litmus cubes were found to be the most satisfactory though the difference between azolitmin and litmus cubes was slight. The other forms of purified litmus are said to have inhibited the growth of bacteria to a noticeable degree.

An electric incubator for bacteriological work, W. M. ESTEN (Connecticut Storrs Sta. Bul. 84 (1915), pp. 139-146, figs. 3).—The author describes an electric incubator which he has made that proves to be inexpensive, serviceable, and durable. One of these incubators, made for the Carnegie Institution of Washington, was 30 by 18 by 14 in. inside measurement and cost, including labor and material, \$70.85. This has been in use for three years and has given excellent satisfaction. A trial incubator made by the author has been in constant use for 10 or 12 years and has proved thoroughly satisfactory.

FIELD CROPS.

[Experiments with field crops in Barbados] (Rpt. Dept. Agr. Barbados, 1914-15, pp. 2-32).—Experiments with sugar cane conducted at 16 estates included a comparison of seedling varieties with the White Transparent as a standard. The results show that B. 6450 yielded on the average 5.76 tons of cane, or 1,727 lbs. of saccharose per acre more than White Transparent, and that B. 6032 yielded on the average 5.57 tons of cane, or 1,334 lbs. of saccharose per acre more than B. 6450. Results are also reported on a comparison of seedling canes, including B. 6450, with White Transparent when grown as plant canes and rattoons on the black and red soils of the island. These results also generally favored the seedling canes. In a fertilizer experiment with sugar cane in which each fertilizer application supplied nitrogen at the rate of 60 lbs. per acre, sulphate of ammonia apparently produced 101 lbs., nitrate of ammonia 334 lbs., nitrolim 495 lbs., and nitrate of lime 547 lbs. of saccharose per acre more than was secured from the use of nitrate of soda.

The results of selection experiments with cotton are reported in tables which also include a description of the different varieties and strains which entered into the test. The work in progress represents an effort to improve the indigenous varieties of cotton.

The results of variety tests with cassava, economic Colocasieæ, Caladiums, and Xanthosomas, leguminous crops, yams, and grasses are presented in tabular form with brief notes.

[Experiments with field crops at the Tortola experiment station], F. Watts (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Tortola, 1914–15, pp. 7–15).—In a variety test with sugar cane harvested as first rattoons, B. 6450 ranked first with a yield of 19.2 tons of cane per acre, and this was the only variety giving a high yield in an unfavorable season. Experiments with cotton varieties showed that St. Vincent was larger and more vigorous than St. Kitts and also exhibited a greater power of resistance to dry weather. In a comparison of cassava varieties, Blancita ranked first with a yield of 7 tons per acre. The results of tests with sweet potatoes in 1914–15 showed the heaviest yields from Harper, Anguilla, and Bourbon, producing 13,024, 11,584, and 10,304 lbs. per acre, respectively. The best yields of peanuts 1,500 lbs. per acre, were secured from the Gambia and Dixie Giant varieties.

Various strains of cotton originated from St. Kitts seed were tested and the yields of seed-cotton were found to range from 988 to 1,118 lbs. per acre. Field and laboratory notes on the cotton-selection work are given.

[Experiments with field crops at the St. Kitts-Nevis experiment stations], F. Watts (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Kitts-Nevis, 1914-15, pp. 2-14).—In a test of 13 varieties of sweet potatoes, Caroline Lee, Playwell, and Brass Cannon ranked first and yielded in the order mentioned over 1,500 lbs. of crop per acre. The results of variety tests with yams in progress for 11 years gave first rank to French No. 3 with an average yield of 14,376 lbs. per acre followed by Jackroe with 12,420 lbs.

Fertilizer experiments conducted with cotton gave the highest increase over the check plat, which received no manure, in the case of the plat receiving nitrogen as nitrate of soda, potash in the form of sulphate, and phosphoric acid as basic slag. The results of fertilizer trials over a period of 11 years are regarded as showing that under the conditions existing at the experiment station where the soil is loose and open, the application of commercial fertilizers is not remunerative.

Notes are given on selection work with cotton, and the results thus far secured are regarded as encouraging although unfavorable weather conditions reduced the yields. Minor experiments with peanuts, guinea corn, maize, tobacco, Rounceval peas, and species of Stizolobium are briefly noted.

[Work with field crops on the government experiment farm at Akola, Berar, for the year 1914-15], J. H. RITCHIE (Dept. Agr. Cent. Prov. and Berar [India] Rpt. 1914-15, pp. 1-15, pl. 1).—A description of the farm is given and the lines of work are briefly noted. The results of experiments are presented in tabular form.

In a rotation experiment cotton followed by wheat and cotton followed by tur proved the most profitable rotations under test. The wider spacing of cotton plants, 15 in. each way or 15 by 20 in., proved most satisfactory, and this is considered due to the selection of seed that has been carried on and which has influenced the branching habit of the plants. Topping cotton plants proved an unproductive practice. Among the varieties, Rosea cotton as in former years proved the most valuable, and selected Rosea gave better returns than the unselected strain. Poudrette was found to be the most economical manure for cotton and juar grown in rotation.

The production of green forage during the entire year, A. C. Tonneller (Min. Agr. Nac. [Buenos Aires], Dir. Gen. Enseñanza e Invest. Agr. [Pub.], No. 41 (1915), pp. 125, pl. 1, figs. 32).—The value of green forage during the entire year and the methods of producing it are discussed. The crops considered in this connection are the soy bean, cowpea, velvet bean, corn, non-saccharin sorghums, millets, barley, vetches, horse bean, lupins, and Jerusalem artichokes. Tables are given showing the composition of the different crops, the time each occupies the land, the number of cuttings, the average quantity of green forage produced, the average rainfall during the growing period, the time of seeding, sprouting, and harvesting, and other popular information of a similar nature.

The number of temporary roots in the cereals, R. G. Wiggans (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 31-37, pl. 1).—This paper reports data gathered with reference to the number of temporary roots in corn, wheat, einkorn, and emmer. The results of the study are given in tables with brief comments. The germination tests from which the data were obtained were made in the laboratory at about optimum temperature and moisture conditions for seed germination. The radicle is considered as the first temporary root and is included in all the figures given.

It is concluded from the results secured that the various groups of corn and of wheat do not have a regular number of temporary roots. The dent corns and pop corns tested had four temporary roots in a greater percentage of cases than any other number. It is believed that the flint and probably the sweet corns have one temporary root in more cases than any other number. The soft corns varied greatly in all cases in the number of temporary roots produced. In the various groups of wheat the greatest percentage produced five temporary roots instead of three as is ordinarily reported.

The production and handling of grain in Argentina, L. Duval (U. S. Dept. Agr. Yearbook 1915, pp. 281-298, pls. 12).—This article describes the cereal producing region of Argentina; points out the importance of cereal and flax production in that country; and describes the methods of growing, handling, and marketing of corn, wheat, oats, and flax, special attention being given to the classes of corn grown, the planting, harvesting, and storing of the crop, and to the seeding, harvesting, and threshing of wheat, oats, and flax. The classes and varieties and types of wheat commonly grown are briefly noted. A description is given of the grain storage facilities of the country and of the classification and inspection of grain and of grain contracts. The use of warehouse certificates in the grain trade is briefly explained.

Seed corn for the 1916 crop, H. D. Hughes and W. W. Stanfield (Iowa Sta. Circ. 28 (1916), pp. 3-16, figs. 6).—The results of a study of seed-corn conditions in the State are reported and methods of testing seed-corn are described. The general survey revealed that in many localities the quantity of seed-corn available was sufficient for planting the next crop provided the corn showing considerable vitality be given the individual ear test to remove the worthless ears.

From tests made at the station the cost was found to be from 15 to 45 cts. for each hundred ears, the difference being due to the method used. The cost of testing by the Rag Doll method was 18 cts. and by the saw-dust box method 27 cts. Complete directions for the use of the Rag Doll tester are given.

During the fall of 1915, 220 lots of seed-corn of 20 ears each were picked on different dates, the first on October 4 and the last or eleventh series of lots on December 13. Two selections were made each week, one of the most mature ears and the other of immature or soft ears. Each of the 4,400 ears was tested late in February. The results showed that of the mature ears picked at weekly intervals and stored in seed houses with continuous heat 74 per cent gave strong germination; the same quality picked at the same time but stored in a closed shed with no artificial heat, 35 per cent; and of those stored in an open shed only 11 per cent gave strong germination. The more immature seed corn picked at weekly intervals and cured and stored in the seed house with artificial heat gave 54 per cent; those in a closed shed 14 per cent; and those in an open shed 10 per cent.

Cotton—varieties and limiting factor tests, W. L. Hutchinson (South Carolina Sta. Bul. 185 (1916), pp. 19).—This bulletin reports some results of experiments with cotton conducted in 1913, 1914, and 1915. The results of variety tests are given in tables with brief comments. The rainfall during the growing season is also shown.

Thirty varieties were tested at the Pee Dee substation in 1914 and 1915, many of the varieties being grown in both years. In 1914, Cook Improved headed the list with a yield of 2,205 lbs. of seed-cotton per acre, 39 per cent of lint, and 860 lbs. of lint per acre, the total value of the crop produced being \$130. The range in lint production for the 30 varieties was from 401 to 860 lbs. per acre and the percentage of lint from 30 to 39. In the test of 1915 the variety Pulnott ranked first in yield of lint per acre with 949 lbs., and in total value of crop with \$146.20 per acre. The range in yield of lint per acre for the 30 varieties this year was from 523 to 949 lbs., and the percentage of lint from 29 to 39. Cook Improved this year ranked third in the yield of lint per acre with 889 lbs., but ranked first in the percentage of lint.

The main station in 1913 tested 21 varieties in small groups. The varieties showing special merit and their yields of seed-cotton per acre were as follows: Simpkins Ideal 1,763 lbs., Petway 1,731 lbs., Kitchings 1,664 lbs., Cook Improved 1,526 lbs., and a hybrid between King and Triumph 1,405 lbs. In a test

of 24 varieties in 1915, Double Limbed stood first in the rate of yield of seed-cotton with 2,442 lbs. per acre, in the yield of lint per acre with 810 lbs., in the yield of seed per acre with 1,632 lbs., and in total value of crop per acre with \$129.84. The range in percentage of lint of the 24 varieties was from 30 to 39 per cent, Cook Improved leading in this respect. In yield of seed cotton per acre the varieties ranged from 1,145 lbs. to 2,442 lbs.

At the Pee Dee substation, experiments were conducted in 1914 and 1915 to determine the limiting factor or factors of cotton production, and a similar test was conducted with corn. The results secured with both crops given in tables show that for the two seasons, nitrogen was the principal limiting factor, but moisture may become the factor which limits the production in some seasons.

Studies on the cotton plant in Egypt, W. L. Balls (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8, pp. 1017-1023, fig. 1).—This article summarizes briefly the work of the author with cotton in Egypt and groups the conclusions arrived at in these studies with reference to agricultural practices, including irrigation, spinning requirements, plant physiology, plant breeding, and genetics. A bibliography of 49 references is presented in conclusion.

Comparative spinning tests of the different grades of Arizona-Egyptian with Sea Island and Sakellaridis Egyptian cottons, F. Taylob and W. S. Dean (U. S. Dept. Agr. Bul. 359 (1916), pp. 20, figs. 2).—A report is presented on spinning tests with the different grades of Arizona-Egyptian cotton compared with each other as to waste, tensile strength, bleaching, mercerization, dyeing, and finishing qualities, and also compared with Sakellaridis Egyptian and Sea Island cottons. The tests were conducted on the 1914 crop and the different lots tested included one bale each of extra, choice, standard, and medium Arizona-Egyptian cotton; three bales of Sakellaridis Egyptian cotton of the grades good, fully good fair, and fair; and two bales of Sea Island cotton of the grades fancy and extra choice. The results are given in tables and are briefly discussed.

The relative waste of the four grades of Arizona-Egyptian cotton was as follows: Extra 17.69 per cent, choice 18.56 per cent, standard 20 per cent, and medium 20.9 per cent. With respect to grade the four bales of this cotton were found to be proportionately less wasty than the two bales of Sea Island, and these again were proportionately less wasty than the three bales of Sakellaridis.

No relation was found to exist between the price of the different kinds of cotton and the percentages of waste discarded in the manufacturing processes. Arizona-Egyptian was estimated to be lower in commercial value than Sea Island and Sea Island lower than Sakellaridis, when equivalent grades were compared. No significant relationship was observed between the tensile strength of the respective grades of Arizona-Egyptian cotton, and the difference in the tensile strength of yarns made from the three kinds was practically negligible, although the average results were somewhat in favor of the Sakellaridis Egyptian cotton with the Sea Island standing second. The tensile strength for the highest number of yarns was in favor of the Sea Island cotton. It is concluded from the results that our domestic cottons are equal and in most respects superior to imported cottons.

The results of a laboratory test indicated that after bleaching, dyeing, and mercerizing, the Arizona-Egyptian and Sea Island cottons were practically equal to each other and slightly superior to the Sakellaridis in their bleaching and mercerizing properties. They were also found to be fully equal to each other in dyeing properties, but in tensile strength the advantage was slightly in favor of the Sea Island and Sakellaridis. The finished gray and mercerized yarns were comparatively equal in luster, the yellow color being a little more evident

in the Arizona-Egyptian than in the Sakellaridis, which in turn was somewhat more yellow than the Sea Island.

Ráb: A unique system of cultivating rice in western India, E. Buok (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8. pp. 1111-1117).—This system is described and discussed with reference to the effect of the different practices which it involves.

It is pointed out that among the general features of the system the more prominent ones are that the rice is transplanted from the seed bed to the field, that the seed bed and not the field is manured, and that by burning the manure its effectiveness is increased. The term "râb" refers to manure burned on the seed beds from which rice plants are transferred to the field, and at one time the manure thus burned consisted mainly of branches and twigs of trees and bushes of the surrounding jungle. The advantages of transplanting and of the manuring of the seed bed are considered and an analysis of the heating effect in its various aspects is presented. It is shown that one of the advantages of transplanting is the possibility of economizing in the use of manures, since their application to the seed bed instead of to the field gives a greater efficiency for a given quantity and incurs less expense in the application.

A study made by H. H. Mann et al. from 1909 to 1912 on the effect of heat on the chemical, physical, and biological character of the soil, the effect of the ash constituents on the plants, and the effect of heat alone compared with that of the ash and of each with that of the complete application used in the "rab" system, is briefly reviewed and the results summarized. In this study the analysis of the water-soluble constituents of the soil before and after heating showed a steady increase in the amounts of soluble minerals and organic matter with increase of temperature. An increase in permeability was found to be proportional to the increase of temperature. A similar increase in permeability brought about by the addition of gypsum was only able to effect an increase in yield of about one-fourth of the amount produced by heating the soil.

With regard to the biological effects of heat on the soil it was found that the activity of the aerobic organisms as measured by the rate of absorption of oxygen was very largely reduced on heating to 125° C. for half an hour, but never wholly destroyed, and that after 7 weeks it greatly exceeded that in the unheated soils. It is concluded that since the growth of the seedlings is greatest immediately after heating when the aerobic activity is lowest, the fertility of the soil is not dependent on the presence of large numbers of soil organisms during the growth of the plants. It is pointed out that investigators have shown that nitrogen in the form of ammonia is the most effective manure for rice and that greater yields are obtained by applying it before planting than at intervals during the growth of the crop, and from this fact it is concluded that the heating effect of the rab system seems to produce ideal conditions in the seed bed as it causes a temporary increase in ammonification of the soil at the most favorable period in the development of the rice plant.

See also a previous note (E. S. R., 27, p. 641).

The cost of producing sugar beets, F. W. Peck (Minnesota Sta. Bul. 154 (1916), pp. 3-35, figs. 11).—The results of a study of the cost of sugar beet production showed that man labor constituted 49.5 per cent of the total cost of production. Without contract help the growers required an average of 155.4 hours per acre to produce the crop. The average cost per acre for both contract and noncontract labor was \$23.61. The average rate per acre for professional labor was \$17.19, or 20.6 cts. per hour. With contract or outside labor the grower spent 34 per cent, and without it 11.5 per cent of his labor in marketing the beets.

Horse labor was found to constitute 21 per cent of the cost, 110.6 horse hours being required, costing at 10 cts. per hour \$11.06. The average of all farms gave a cost of \$9.97 per acre for horse labor, of which one-third was spent in marketing the beets.

The average rate of seeding was 17 lbs. per acre at a cost of \$2.57 with the seed at 15 cts. per lb. The machinery cost varied with the use or nonuse of the manure spreader, but averaged \$1.21 per acre. Commercial fertilizer was applied in 5 of the 11 localities studied, but the results in yields gave no indication of its value. The average cost per acre was \$1.78 for about 120 lbs. On these farms from 6 to 16 loads of manure were usually applied for the beet crop and the labor of application, the only charge made, amounted to \$3.66 per acre. Land rental constituted 15 per cent of the total cost, the average cash rental paid and interest at 6 per cent on owned land amounting to \$7.74 per acre.

The total cost of production per acre was \$47.65. On the average normal yield basis of 9.82 tons per acre, the cost was \$4.85 per ton. The receipts were \$5 per ton in each case, leaving a profit of 15 cts. or \$1.45 per acre. In addition to this the producer received \$7.74 per acre as land rent and \$23.31 as pay for his own labor, a total income over other expenses of \$32.50 per acre. With the employment of contract labor, the producer had \$15.31 per acre for rent, for his own labor, and for profit.

The yields varied from 5 to 22 tons per acre with a normal average for the three years of 9.82 tons. The average of the estimates of the value of beet tops by the growers was \$4.40 per acre. It was also estimated that an increase of 6 bu. of wheat and of 4 to 6 bu. of barley and oats may be expected when these crops follow sugar beets.

Sweet potato culture in Arkansas, W. H. Wicks (Arkansas Sta. Bul. 124 (1915), pp. 3-31, figs. 21).—This bulletin is a brief popular treatise on the culture of sweet potatoes in Arkansas. The topics discussed are location of field, selection of seed, varieties, propagation, the soil—its preparation and fertilization, planting, cultivation, harvesting, storing, and marketing. Notes are also given on the importance of the sweet potato industry of the State, and on the cost of production and the returns that may be expected.

The fire-holding capacity of tobacco leaves as a factor in tobacco breeding, D. Hoffmann (Fühling's Landw. Ztg., 64 (1915), No. 13-14, pp. 366-371).—
This article discusses the importance of the fire-holding capacity of tobacco leaves, and points out certain difficulties encountered in breeding for a high quality in this respect. A report is also given of counts made to determine the possible seed production of tobacco plants and of the length of time the leaves of certain selected plants continued to glow in a burning test.

The results of the seed counts indicated that an average plant may produce 202,300 seeds. In 1914 the duration of glow of 150 unfermented leaves ranged from 10 seconds to the complete incineration of the leaf. Fire-holding capacity appeared to be a heritable character. It is stated that the plants under test were selected on the basis of color and structure of leaf, characteristic of plants with a high potash content, and of early maturity.

Alaska and Stoner, or "Miracle" wheats: Two varieties much misrepresented, C. R. Ball and C. E. Leighty (U. S. Dept. Agr. Bul. 357 (1916), pp. 28, figs. 6).—The history of the two varieties of wheat is reviewed at some length, and the results of comparative tests made by several experiment stations and this Department are presented in tabular form and discussed.

In summarizing the experimental results it is pointed out that Alaska wheat has failed to produce even fair yields when tried in many parts of the country,

and that it is not as good a milling wheat as many other widely grown varieties. It is further concluded that Stoner wheat does not differ essentially in value from many other wheats now widely grown in the eastern United States. The variety did not outyield all varieties in any of the tests made nor did it rank above all others in tillering capacity. The use of 20 to 30 lbs. of seed per acre was found insufficient for the production of maximum yields.

The seed field, H. L. Bolley (North Dakota Sta. Circ. 12 (1916), pp. 4).—Brief popular directions are given for growing seed of different farm crops on the farm.

Agricultural seed, G. P. Burns (Vermont Sta. Bul. 192 (1916), pp. 3-40).—
A report is made in tabular form on the analysis of 343 samples of agricultural seed offered for sale in the open markets of Vermont. The guarantied and actual purity percentages and the approximate number of weed seeds in a pound are given, together with the amount of ergoted grain found in the timothy and red-top samples. In discussing the results of the inspection it is pointed out that of 337 samples 204 were equal to or better and 133 were below the standard of purity proposed by this Department. A synopsis of the Vermont seed law setting forth the duties of the wholesaler, retailer, and the station is presented, and advice to the farmer regarding the purchase of seed and the use to be made of the seed analyses published by the station under the law is given.

How seed testing helps the farmer, E. Brown (*U. S. Dept. Agr. Yearbook 1915, pp. 311–316, pls. 2*).—The inefficiency of certain state seed laws is pointed out in this article, together with the influence of the enforcement of the federal seed importation act on the quality of imported seeds. Some of the practices in adulterating seeds are briefly noted. A list of publications of this Department which bear on the testing of seeds is given. It is stated that seed testing helps the farmer by telling him what part of the seed is alive, of what kinds it consists, and how many weed seeds it contains, and also by furnishing the means of discovering and preventing the sale of adulterated and low-grade seeds.

It is reported that tests of samples of foreign seed showed that between July 1, 1914, and October 1, 1915, over 300,000 lbs. of light-weight orchard grass seed was imported which contained an average of only 28 per cent of seed, the remainder being chaff and dirt. Nearly 2,500,000 lbs. of crimson clover seed imported during the 6 months following April 1, 1915, contained an average of only 54 per cent of live seed, and of this quantity the germination of 500,000 lbs. averaged but 38 per cent. It is also mentioned that in the spring of 1915 the importation of rape seed resulted in market supplies of three distinct plants sold as winter rape: (1) Winter rape, a biennial forage crop with fleshy, succulent roots, furnishing an abundance of forage the first year and seeding the second year after planting; (2) oil-seed rape similar to winter rape in its early stages but maturing seed in midsummer of the first year of growth; and (3) turnip rape, an oil seed producing turnip of but little forage value as compared with winter rape.

HORTICULTURE.

China. a fruitful field for plant exploration, F. N. MEYER (U. S. Dept. Agr. Yearhook 1915, pp. 205-224, pls. 8, fig. 1).—This comprises a popular resume of the author's explorations in China in search of information relative to plant industries and plant material that might be adapted to conditions in the United States.

A genetic analysis of horticultural varieties propagated by vegetative means, D. F. Jones (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 137-141).—A short paper on this subject in which the author advocates an analytic study of plant varieties usually propagated by vegetative means before attempting to improve such plants by breeding operations.

Myrtaceous possibilities for the plant breeder, P. J. Wester (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 3, pp. 207-215).—In continuation of a previous article dealing with the annonas (E. S. R., 29, p. 642) the author here describes 64 species of myrtaceous plants with edible fruit of which 20 belong to the genus Psidium, 19 to the genus Eugenia, and scattered species to 13 other genera. The subject matter is presented with the view of calling the attention of horticulturists and breeders to the valuable plant material among the myrtaceous plants.

Garden calendar for 1916 (Montgomery, Ala.: Agr. and Indus. Dept., Immigr. and Markets Bur., 1916, pp. 2).—This calendar, which is prepared with special reference to Alabama conditions, contains notes on flower plantings, succession crop combinations for vegetables, and vegetable planting tables.

Fungicide and insecticide inspection (Maine Sta. Off. Insp. 75 (1916), pp. 8).—A report on analyses of 33 samples of fungicides and insecticides analyzed by the station during 1915, with a discussion by A. M. G. Soule.

[Spraying in Oregon] (*Oreg. Agr. Col. Bul. 228* [1916], pp. 32).—This bulletin consists of two sections. The first, on Orchard Spraying in Oregon, 1916, by H. P. Barss and A. L. Lovett (pp. 3–24), gives information relative to the more important diseases and insect pests of various orchard fruits and their control, including directions for making spray mixtures. In the second, Spraying Machinery, by V. R. Gardner (pp. 25–32), the author calls attention to the adaptation of spray machinery of different types to particular orchard conditions.

Report of the experimental fields of the Chamber of Agriculture of the Province of Hanover in Poppenburg for the year 1914, O. Hollmann (Landw. Jahrb., 48 (1915), No. 5, pp. 659-716, pls. 10, fig. 1).—Experiments conducted with peas, beans, and cabbage in 1914 are reported. The experiments deal chiefly with cultural methods, variety tests, and methods of controlling diseases.

Asparagus, R. W. DeBaun (New Jersey Stas. Circ. 57 (1916), pp. 4).—This circular discusses the method of establishing an asparagus field, planting, care the first season, care during and after the cutting season, fertilizers, insect enemies and disease, and harvesting the crop.

Sand for cabbage seed bed, M. G. Kains (Country Gent., 81 (1916), No. 14, p. 745).—In connection with a study of the effects produced by various soil mixtures on the root development of early cabbage being conducted at the Pennsylvania Experiment Station, preliminary results indicate the desirability of using for the seed bed a soil composed largely of sand. The sand seems to stimulate the development of roots by forcing them to reach for food and at the same time retards the early development of tops. Because of their strength the plants seem to be able to resist disease to a greater extent than do plants grown by the ordinary methods.

Studies in lettuce breeding, C. E. Durst (*Proc. Soc. Hort. Sci., 12* (1915), pp. 96-98).—This paper discusses chiefly crosses made at the Illinois Experiment Station between open heading and close heading varieties of lettuce.

Inheritance in tomatoes, G. W. Hoop (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 88-95).—The experiments here described were started by the author at the Michigan Experiment Station in 1912 and later continued at the Nebraska Sta-

tion, where the F_2 and succeeding generations were grown. A number of crosses were made with the object of studying the unit characters found in dwarf and standard varieties as well as to produce some superior commercial variety. Data secured from various crosses of F_1 and F_2 generations are here presented and discussed.

Tomato growing in California, S. S. Rogers (California Sta. Circ. 147 (1916),

pp. 12).—A revision of Bulletin 239 (E. S. R., 29, p. 540).

Acreage of fruits in California, bearing and nonbearing, in 1915, G. P. Weldon (Cal. Fruit News, 53 (1916), No. 1450, p. 5).—A statistical compilation showing the bearing and nonbearing acreage of various fruits and nuts in California in 1915.

Orchard management investigations, J. OSKAMP (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 44-47).—In this paper the author briefly outlines an experiment in orchard soil management which has been under way in southern Indiana for a period of five years. No results are presented in this paper.

Orchard economics, M. W. RICHARDS (*Proc. Soc. Hort. Sci., 12 (1915), pp. 47-50*).—A discussion of management costs reported from a representative apple orchard included in the system of community demonstration orchards inaugurated by the Purdue Experiment Station some five years ago.

The water supply and fruit bud formation, W. Paddock (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 51-54).—In this paper the author reviews some data secured in orcharding experiments at the New Hampshire Experiment Station (E. S. R., 33, p. 44) with the view of showing that the amount of moisture present in the ground about the time when fruit buds begin to differentiate is an important factor in the development of fruit buds.

The science of orchard heating, C. Nichols (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 22-27).—This comprises a brief review of the history of the development of frost protection devices, including brief descriptions of a number of forms now in use.

The root systems of nursery apple trees, J. K. Shaw (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 68-72).—In this paper the author discusses chiefly the influence of different apple scions on the root systems usually employed for grafting apple trees. A number of observations based on an investigation of the interrelation of root and scion in apples started at the Massachusetts Experiment Station in 1912 are also presented.

The results of apple pruning investigations, W. H. ALDERMAN (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 54-59).—This comprises a preliminary report of experiments started by the West Virginia Experiment Station in 1911 in which trees in several orchards were given varying amounts of dormant pruning. The results secured in the various orchards are here grouped together and discussed with special reference to the effect upon vigor, growth, and fruitfulness of the amount of pruning and season of pruning.

Thus far the results secured indicate that heavily pruned trees do not make as satisfactory a gain as lightly pruned trees, either in total length of growth or in increase of trunk diameter. In young trees heavy pruning has delayed fruit bearing and light pruning encouraged it. In old trees that have been bearing for some time and were in a fair state of vigor at the beginning of the experiment, the vigorous pruning stimulated fruit production.

With reference to difference in season of pruning, in every case either heavy or moderate dormant pruning stimulated a greater growth than any of the summer prunings. The reduction in vigor was less in the case of early summer pruning than in either repeated or midsummer prunings. Summer pruning caused a great decrease in the size of leaf, number of leaves per tree, and total

leaf area per tree. The leaves were also deficient in chlorophyll. Data secured in young orchards indicate that summer pruning has a detrimental effect, if any, with reference to early bearing. Merely corrective dormant pruning far exceeded all forms of summer pruning in bringing about early bearing and in some cases the moderate and heavy dormant pruned trees produced more bountifully than did the summer pruned trees.

Some points on the general care of apple orchards, J. P. Stewart (*Proc. State Hort. Assoc. Penn.*, 55 (1914), pp. 89-95, pl. 1).—In the present article consideration is given to methods of securing early bearing, the control of aphids and red bugs, and the fruit pit disease or "stippen." A provisional list of varieties with reference to their susceptibility to fruit pit is also given.

Irrigation of peaches, L. D. BATCHELOR (*Utah Sta. Bul. 142 (1916*), pp. 3-23, figs. 13).—This bulletin presents the results of irrigation experiments started in a 3-year-old peach orchard in 1912.

Data secured in 1913–14 showed that frequent applications of irrigation water applied to peaches on a gravel loam soil at intervals of 7 or 8 days produced a more continuous and greater total twig growth than the same total amount of water applied with larger applications at intervals of every 10 to 12 days. The more porous the soil the more frequently the trees should be watered.

Evidence was secured showing that the trees may receive an unnecessary amount of water. The maximum duty of irrigation water applied to peaches on a gravelly soil was 31 acre-inches during the years 1913 and 1914. This amount of water produced a total twig growth practically equal to that produced by 62 acre-inches of water.

With the same total amount of water applied on a gravel loam, there is a regular increase in crop production the more frequent the irrigation. No amount of water applied early in the season to a crop of peaches on a gravelly soil will compensate for the lack of water during the month before harvest.

Poor color of fruit was associated with an insufficient amount of irrigation water. High color of fruit was associated with late watering, that is, watering at intervals during the latter part of the growing season up to harvest time.

Some peculiar forms of winter injury in New York State during the winter of 1914–15, W. H. CHANDLER (*Proc. Soc. Hort. Sci., 12 (1915), pp. 118–121).*—The author describes a form of winter injury to peach buds observed in the spring and summer of 1915 in which the pith of the bud and even the pith of the twig at the base of the bud was injured, there being also a slight injury to the xylem and some to the cortex. The apparent result of this injury was a retardation of the blooming and leafing period of from 2 to 3 weeks. As the summer progressed a normal crop of fruit was developed and matured at approximately the same time as that on trees with uninjured fruit buds.

Similar observations were made on pear trees. In the case of the pears, however, the entire fruit spurs on many trees were injured, this resulting in the loss of the crop. Where the injury did not cover all of the spur the trees showed some recovery.

A stone-fruit spray made from hydrated lime and sulphur, G. C. STARCHER (Virginia Sta. Bul. 210 (1916), pp. 3-14, fig. 1).—Preliminary field experiments were conducted in 1915 to determine the value of hydrated lime and sulphur as compared with the usual sulphur sprays used for stone fruits. A series of laboratory studies was also conducted relative to the constancy and methods of preparing the hydrated lime and sulphur solution.

As tested for one season the hydrated lime and sulphur solution gave good results as a fungicide with very little spray injury. In view of these results

and the advantages in preparation over the ordinary sulphur sprays, it is recommended to peach growers for trial on a limited scale.

A spraying schedule is given for insects and fungus diseases of the peach in which hydrated lime and sulphur is substituted for the summer treatment of self-boiled lime-sulphur.

Some results in the breeding of small fruits, R. D. Anthony (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 121-125).—This paper discusses some results secured in breeding work with raspberries and strawberries which is being conducted at the New York Geneva Station. The subject matter is discussed under the following general headings: Purple raspberries, dwarf types in raspberries, a correlation in leaf and fruit color among raspberries, and inheritance of sex in strawberries.

Fragaria virginiana in the evolution of the garden strawberry of North America, S. W. Fletcher (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 125-137).—In this paper the author presents considerable evidence to support the conclusion that the garden strawberry of North America is of mixed origin, with *F. virginiana* and *F. chiloensis* predominating.

Experiments with stocks for citrus, W. W. Bonns and W. M. Mertz (California Sta. Bul. 267 (1916), pp. 275-301, figs. 12).—The authors give a brief review of the literature dealing with the use of various stocks for citrus and describes experiments with citrus stocks being conducted at the Riverside Citrus Station. The principal results to date as measured by the first five crop years are substantially the same as those noted in a previous summary of the work (E. S. R., 33, p. 736).

The pitanga, A. D. SHAMEL and W. POPENOE (Jour. Heredity, 7 (1916), No. 4, pp. 179-185, figs. 2).—A descriptive account of the pitanga (Eugenia uniflora) with reference to its botany, distribution, habits of growth, the fruit and its uses, propagation, and culture.

A spotting of citrus fruits due to the action of oil liberated from the rind, H. S. Fawcett (California Sta. Bul. 266 (1916), pp. 261-269, figs. 2).— This bulletin describes experiments made by J. D. Culbertson and the author with the view of determining the cause of "green spot" on citrus fruits, more especially lemons.

The experiments show that at least one of the causes of such spotting is due to the effect of small quantities of oil liberated from the glands in the rind. The oil liberated from the rind by any cause appears to act powerfully and quickly upon all the cells at the surface with which it comes in contact, except those immediately surrounding the oil glands. The affected spots remain green while the remainder of the rind colors normally. Such fruits may be kept for weeks without enlargement of the spots and without change in their green color. Sometimes the green is replaced after a long time by a reddish or brownish color. This lowers the grade of the fruit but usually does not injure seriously its keeping quality.

A number of experiments were conducted with oil squeezed directly from the living rind of the fruit and also with measured quantities of commercially expressed lemon oil. The results of these experiments are summarized as follows: "The effect of a given amount of oil from the rind was greater on fruit in a moist atmosphere than on similar fruit in a dry atmosphere. The moisture being the same, the effect was greater on green or immature fruit than on fully colored or mature fruit. The effect was greater on fruit just picked than on similar fruit picked for some days. The action of small amounts of oil, for example, such as could be liberated by a hard pressure of the thumb against the rind of a dark-green freshly picked moist lemon (or by 0.01 cc. of the com-

mercially expressed lemon oil) was sufficient to cause the typical green spotting. The green color appeared to be fixed in the portion acted on by the oil, while the remainder of the rind colored normally in the usual process of curing in four to six weeks. The action of a large amount of lemon oil, such as 0.1 cc. or more, under the same conditions caused the spots to become brownish or reddish rather than green. When the amount was sufficiently increased the breaking down of the tissue was so great that blue mold started in a few days. When the fruits acted on by the oil were left attached to the tree, only in rare cases did the green color remain. As the fruits continued to grow and mature, the sunken areas were partially restored and only slight scars were left.

"Under similar conditions the oil from the rind of oranges acted upon other uninjured oranges in the same manner as did the oil from the rind of lemons act upon other lemons. The oil caused the spotting of tender leaves and shoots and the withering of flower buds when squeezed out upon them. The action of the oil on the surface of the rind is extremely rapid, as shown by the fact that 0.01 cc. of lemon oil acting for eight seconds was sufficient to show afterward a visible effect on the rind."

Green spotting has been observed almost exclusively on fruit picked during the late fall, winter, and early spring, which period corresponds to the season of moist atmospheric conditions in California, due to frequent rains and fogs. The remedial measures suggested by the present investigations are picking the fruit when free from rain or dew and the use of extreme care in handling fruit to avoid injuries or knocks that would tend to liberate the oil in the rind.

Cacao culture, A. RIBEIRO DE CASTRO SABRINHO (O Cacauzeiro e Sua Cultura Intensiva. Rio de Janeiro: Min. Agr., Indus. e Com., 1915, pp. 25).—A treatise on cacao culture, including information relative to climatic and soil requirements, varieties, propagation, planting, cultural operations, intercrops, methods of harvesting, and preparation for market. A brief bibliography on cacao culture is included.

The date palm in Egypt, T. W. Brown (Agr. Jour. Egypt, 5 (1915), No. 1-2, pp. 63-79, pl. 1).—An account of the date palm with reference to methods of propagation, planting operations, irrigation, soil, manures, intercrops, rate of growth, and the peculiarities of the male and female palms, with special reference to the process of hand pollination.

Report of the proceedings at the sixth annual meeting of the Northern Nut Growers' Association, Rochester, N. Y., September 1 and 2, 1915 (North. Nut Growers Assoc. Proc., 6 (1915), pp. 77).—In addition to the usual business of the association the following papers read at the meeting, together with a bibliography of the year of articles dealing with nuts and various phases of nut culture, are given: The Relation of Forest Conditions in New York to Possibilities of Nut Growing, by H. P. Baker (pp. 17–23); [Nut Survey of Pennsylvania], by F. N. Fagan (pp. 23–27); New Tree Crops and a New Agriculture, by J. R. Smith (pp. 30–35); Notes on the Hazels, by R. T. Morris (pp. 36–51); An Appeal to Owners of Hardy Nut Trees, by C. A. Reed (pp. 51–57); History, Dimensions, and Crop Records of Parent Northern Pecan Trees, and Notes on the Observation of Propagated Trees, by W. C. Reed (pp. 58–62); Walnut Observations in California, by L. D. Batchelor (pp. 63–68); Pruning the Persian Walnut, by J. G. Rush (pp. 69, 70); and Report on Nut Growing in Canada, by G. H. Corsan (pp. 71, 72).

Lawn making in California, J. W. Greeg (California Sta. Circ. 149 (1916), pp. 8, fig. 1).—This circular contains practical directions for the construction and maintenance of lawns, including also information relative to methods of controlling the weeds, rodents, and insects in lawns.

FORESTRY.

Forest conservation for States in the southern pine region, J. G. Peters (U. S. Dept. Agr. Bul. 364 (1916), pp. 14).—This bulletin points out the essential elements in the various forest problems that confront the States in the southern pine region, shows how these problems are interrelated, and discusses methods for solving them, information being given relative to conservation legislation already in force in the different States and the nature of the assistance the Federal Government is prepared to offer to forestry in these States.

Renewing the shelter-belt, G. B. MacDonald (*Iowa Sta. Circ. 27* (1916), pp. 16, figs. 18).—This circular describes the following five methods for renewing the shelter-belts in Iowa: Regeneration from one side, regeneration from two sides, regeneration by clear cutting, regeneration by alternate rows, and regeneration by under planting. Each method is illustrated with drawings explaining how the work is carried on for a shelter-belt of average size, and a list is given of tree species suitable for use in the method.

Report on the activities of the Swedish Institute of Experimental Forestry during the 3-year period, 1912–1914, G. Schotte and H. Hesselman (Meddel. Stat. Skogsförsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens), No. 12 (1915), pp. 9-70. I-XX, fig. 1).—In addition to a brief statement of progress made in various divisions of the institute a schedule of investigations and other projects for the period 1915–1917 is also given.

Progress report of forest administration in the Province of Assam for the year 1914–15, A. R. Dicks and W. F. L. Tottenham (Rpt. Forest Admin. Assam, 1914–15, pp. [6]+26+53+5, pl. 1).—The usual progress report relative to the administration of the state forests in the Western and Eastern Circles of the Province of Assam, including a financial statement for the fiscal year 1914–15. All important data relative to alterations in forest areas, forest surveys, working plans, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Two forest arboretums near Brussels, D. E. HUTCHINS (*Trans. Roy. Scot. Arbor. Soc.*, 30 (1916), pt. 1, pp. 1-14).—Notes are given on the growth of various species of trees in the Groenendaal and Tervueren arboretums near Brussels.

The development of the vegetation of New York State, W. L. Bray (N. Y. State Col. Forestry, Syracuse Univ. [Pubs.], 16 (1915), No. 2, pp. 186, pls. 2, figs. 5.2).—This study comprises as a whole an analysis of the history and present aspects in the development of the native vegetation in New York State, together with some consideration of the status of vegetation as modified by human action. The study was conducted with reference to its subsequent value in investigations along various phases of forestry and allied lines of work, such as fish and game propagation and protection and the control of injurious insects and fungi.

The subject matter is treated at length under the following general headings: A general review of classification, growth forms, and plant associations; landmarks in the geological history of vegetation; the glacial period and its effect upon vegetation; modern aspects of the plant geography of New York; the content zonal relations, zonal features, and extra-continental relations of the New York flora; the sources of New York flora in general; development of vegetation as influenced by the substratum and the resulting influence upon the substratum; the bog sequence of vegetation; the development of vegetation upon a substratum subject to prevailing water deficit; the resemblance between heath bog and pine barren vegetation; general survey of xerophytic succession in New York; the development of mesophytic vegetation; climax vegetation; and

the status of New York vegetation under cultural conditions. A map showing the dominant trees in different sections of the State is appended.

The evergreens of Colorado, B. O. Longyear (Fort Collins: State, 1914, pp. 80, figs. 58).—This publication contains popular descriptions of the native evergreens of Colorado and also discusses the uses of evergreens, both from an ornamental and economic standpoint; methods of propagation and culture; and insect pests and diseases.

Qualities and uses of the woods of Ohio, W. R. LAZENBY (Ohio State Univ. Bul., 20 (1916), No. 9, pp. 75-111, figs. 18).—In this paper the author reports studies relative to the structure and physical properties of woods taken from Ohio trees. Tabular data show the weight of the various woods in pounds per cubic foot and in kilograms per cubic decimeter.

Tests were made of 69 samples representing 62 species of hardwoods with the view of determining the relative rapidity of absorption and the amount of moisture absorbed by air-dried samples of Ohio woods, and the results are presented in tabular form and discussed. The data given show the weight in grams of water absorbed in seven days, as well as the original volume in cubic centimeters and the amount and percentage of increase in weight and volume.

Similar data are also presented on tests conducted with eight coniferous species of Ohio.

The paper concludes with an account of the kinds and quantities of woods used in Ohio and a classification of the principal and minor uses of various Ohio woods, as well as a list of useful products from wood and parts of trees.

Durability of timbers, P. Groom (Trans. Roy. Scot. Arbor. Soc., 30 (1916), pt. 1, pp. 44-46).—An examination of the statistics dealing with the durability of various European and Indian timbers led the author to conclude that the color of the heartwood is no safe guide to the durability of wood. Although the most perishable woods appear generally to be light-colored, there are dark-colored woods which are by no means durable and some light-colored woods of exceeding durability. The present observations are in opposition to Mayr's law which states in substance that the more intense the color of the heartwood of timber the more durable it is.

Wood as building material, G. Lang (Das Holz als Baustoff. Wiesbaden: C. W. Kreidels, 1915, pp. XXI+388, pls. 2, figs. 214).—A manual of information relative to the growth, structure, physical properties, and uses of the more important woods.

Pointers on marketing woodlot products, S. L. Wolfe (U. S. Dept. Agr. Yearbook 1915, pp. 121-130, pls. 4).—In this paper the author offers a number of suggestions aimed to assist the farmer in securing the maximum returns from his woodlot.

Volume tables for timber estimating, T. Johnson (Massatabeller för Träduppskattning. Stockholm: Zetterlund & Thelanders, 1915, 3. ed., pp. 96, figs. 3).—This comprises tables for estimating the contents of logs and standing timber.

Success of aeroplane patrols, F. B. Moody (Canad. Forestry Jour., 12 (1916), No. 4, pp. 471, 472).—This note calls attention to the successful use of the aeroplane in detecting forest fires during the fire season of 1915 in Wisconsin.

Forest protection in Canada, 1913–14, C. Leavitt, C. D. Howe, J. H. White, Et al. (*Toronto: Com. Conserv. Canada, 1915, pp. XIV+317, pls. 31, figs. 6*).—This report comprises a compilation of information dealing with forest protection in Canada collected under the direction of the committee on forests during the years 1913–14.

Part 1 treats at length of the railway fire situation and part 2 consists of reports of the committee on forests of the Commission of Conservation. The succeeding parts deal with forest fires and the brush disposal problem; the effect of repeated forest fires upon the reproduction of commercial species in Peterborough County, Ontario; the reproduction of commercial species in the southern coastal forests of British Columbia; and forestry on Dominion lands. Regulations governing the granting of yearly licenses and permits to cut timber on Dominion lands are appended.

Proceedings of forest industry conference of the forest protective organizations of the Pacific coast, composing the Western Forestry and Conservation Association, with state, federal, and British Columbia forest agencies, San Francisco, October 19, 20, 1915 (Proc. Forest Indus. Conf. West. Forestry and Conserv. Assoc., 1915, pp. 31, figs. 10).—In this report the following papers are included: Year's Results of Private and State Protective Work, by E. T. Allen (pp. 4, 5); The Government's Experience and Conclusions, by A. S. Peck (pp. 5-7); What the Season Taught British Columbia, by M. A. Grainger (p. 7); Fire Weather Forecasts, by E. A. Beals (pp. 7, 8); Railroad Fires, by F. A. Silcox (pp. 8, 9); Forest Protection and Modern Invention, by C. Du-Bois (pp. 9-11); The Psychology of Sentiment Making, by E. T. Allen (pp. 11, 12); The Business End of Cooperative Fire Work, by A. W. Laird (pp. 12-15); Compulsory Protection Laws, by C. S. Chapman (pp. 15, 16); Relations Between Eastern and Western Forestry Organizations as the East Hopes to See Them, by H. S. Drinker (pp. 17, 18); Our Relations as the West Hopes to See Them, by F. C. Knapp (pp. 18, 19); What the Magazine Can Do To Help, by P. S. Ridsdale (p. 19); Organization of Forest Owners in the East, by W. R. Brown (pp. 19, 20); Can Manufacturers, Timber Owners, and Protective Agencies Unite to Advantage? by H. D. Langille (pp. 20-22); Does the Lumber Industry Need Radical Reorganization to Protect Both Producer and Consumer? by E. B. Hazen (pp. 22-25); The Government and the Lumber Industry, by H. S. Graves (pp. 25-27); and Taxation and Forestry, by E. A. Selfridge, Jr. (pp. 27, 28).

The utilization of wood waste, E. Hubbard, trans. by M. J. Salter (London: Scott, Greenwood & Son, 1915, 2. rev. ed., pp. XVI+192, figs. 50).—This translation of the second edition of the author's work (E. S. R., 14, p. 1132) has been revised and enlarged to include more recent information relative to more advantageous methods of utilizing all wood waste.

DISEASES OF PLANTS.

Fruit and vegetable diseases and their control, E. C. STAKMAN and A. G. Tolaas (Minnesota Sta. Bul. 153 (1916), pp. 3-67, figs. 32).—This is a somewhat popular builetin designed to give information regarding the plant diseases occurring in orchards and gardens in Minnesota. After preliminary directions regarding spraying, formulas are given for a number of the more efficient fungicides which are recommended. The diseases are described under an alphabetical arrangement of the host plants. A spray calendar for the control of insect and fungus pests on the more common orchard and garden plants concludes the bulletin.

Penicillium avellaneum, a new ascus-producing species, C. Thom and G. W. Turesson (Mycologia, 7 (1915), No. 5, pp. 284-287, figs. 3).—A description, together with cultural data, is given of P. avellaneum n. sp.

The genus Rhizoctonia in India, F. J. F. Shaw and S. L. AJREKAR (Mem. Dept. Agr. India, Bot. Ser., 7 (1915), No. 4, pp. 177-194, pls. 6).—Following up a previous account of work by Shaw on Rhizoctonia (E. S. R., 28, p. 149), the

149

authors herein give attention to R. napi and R. destruens, said to be of some economic importance in India. They also give a further discussion of the host relations as noted in India of R. solani, thought to be identical with R. medicaginis, and those of Rhizoctonia sp., said to have as its perfect stage Corticium vagum. The experiments and views of several authors are cited as regards the control of Rhizoctonia disease of economic plants.

Tests of spraying compounds (Jour. Agr. [New Zeal.], 10 (1915), No. 1, pp. 35-40).—Besides reports on tests with insecticides, results are given of trials made with several brands of fungicides by growers in cooperation with orchard instructors and managers of experiment farms in different districts of New Zealand. The discrepancies observed in the values are thought to be partly accounted for by regional and seasonable differences.

Tests of spraying compounds: Lime sulphur, T. W. Kirk (Jour. Agr. [New Zeal.], 11 (1915), No. 2, pp. 129-134).—Reporting on a continuation of the spraying tests noted above, the author states that as first used lime sulphur of American brands was found to do immense damage by scorching. Subsequent tests with modified strengths have shown its adaptability to local conditions, so that by its adoption a considerable reduction may be effected in the employment of Bordeaux mixture, which is found to produce a russeting effect on the fruit. A formula is given for a homemade solution of lime sulphur which is claimed to be as effective as the commercial preparation and less expensive. Results are given following tests of several brands as carried out in the Hawke's Bay district and reported by J. A. Campbell. Further tests are noted below.

Tests of spraying compounds: Lime sulphur, G. Stratford (Jour. Agr. [New Zeal.], 11 (1915), No. 3, pp. 243-247).—In continuation of the above reports, an account is given of the work as carried out in the Nelson district. The four brands of lime sulphur employed are regarded as effective fungicides, and it is thought that this preparation may largely take the place of Bordeaux mixture, which in this district also produces a russeting of the fruit.

As regards powdery mildew, which is said to be gradually increasing in almost all districts, lime sulphur is considered to be the only spray which can combat it successfully.

Disinfection of seed grain with hot water, H. M. QUANJER (Ontsmetting van Zaaigranen met Heet Water. The Hague: Dir. Landbouw, 1914, 2. rev. ed., pp. 18, pl. 1).—This is a discussion of several cereal diseases which may be introduced with the seed grain, those diseases control of which is possible or practicable, the suitability in particular of the hot-water treatment, its mode of application, and the expense connected therewith.

Review of measures taken in the Netherlands for control of grain and grass smut, and streak disease, H. M. QUANJER and J. O. BOTJES (Meded. Rijks Hoogere Land, Tuin en Boschbouwsch. [Wageningen], 8 (1915), No. 3, pp. 129-160, pls. 3).—This contribution, besides discussing the results of previous tests by other investigators and referring to the work of Quanjer (E. S. R., 30, p. 241), gives results of work by Quanjer on smut control and by Botjes on the sensitivity of various grains to copper sulphate and hot water. The latter treatment appears to be generally preferable, both on account of its results and because machinery for its cooperative employment is often already available in the appliances of dairy and laundry plants, the latter offering especial advantages as regards the drying of the grain after treatment so that it can be

The hastening of germination by both the hot water and the copper sulphate treatment is to be made the subject of further study and report.

Mildew of cereals in France, G. GAUDOT (Jour. Agr. Prat., n. ser., 28 (1915), No. 54, pp. 520-522, figs. 2).—This is a brief account of a report by Arnaud already noted (E. S. R., 34, p. 243) regarding the appearance of Sclerospora macrospora on cereals in France.

Club root, A. H. Cockayne (Jour. Agr. [New Zeal.], 11 (1915), No. 3, pp. 197-203, figs. 3).—Club root is said to attack a number of cultivated crucifers and several weeds of the same family in New Zealand, where it is widely disseminated, being found in all classes of soils. It is thought that its appearance in calcareous soils may be due to the leaching of the lime from the upper layers in such localities, as acid soil conditions are much more favorable than alkaline to its development. The excrescences, due to a slime mold (Plasmodiophora brassica), are distinguished from swellings somewhat similar externally but caused by nematodes or else by hybridization. The organism is commonly distributed by the feet of stock.

Leguminous crops offer a ready means of rotation, which should be employed in connection with liming. Artificial fertilizers appear to increase the development of club root. The use of basic manures is advised. Basic slag has given good results in parts of the North Island. Certain varieties of swedes appear to be relatively resistant.

The potato blight in India, J. F. Dastur (Mem. Dept. Agr. India, Bot. Ser., 7 (1915), No. 3, pp. 14, pl. 1).—It is stated that late blight or leaf curl (Phytophthora infestans) of potato, which is prevalent in the hills in India, first made its appearance in the plains in 1899–1900. It disappeared after three or four years, but reappeared in a violent outbreak in 1912–13 at Bhagalpur and Rangpur, attacking also the tomato crop at the latter place. This latter appearance is ascribed to the use of seed tubers from Darjeeling and Naini Tal, where the disease seems to be present each year. Experiments and observations since carried out appear to show that the summer heat of the plains is sufficient to kill the parasite. It is accordingly recommended that seed procured from infected localities be obtained early enough to allow them to pass some part of the summer on the plains.

The gross and minute alterations in the plant due to the attack and progress of the parasite are described, more particularly the developmental phases of the haustoria and the influence of the fungus in producing deformation of the starch granules. Certain bodies regarded as resting conidia, produced in pure cultures on artificial media, are also discussed.

Late blight of potato, R. A. Jehle (Estac. Expt. Agron. Cuba Circ. 48 (1915), pp. 3-6, pls. 4).—This contains a brief discussion of the late blight of potato, due to Phytophthora infestans, which is is said to cause in Cuba the loss of a large part of the crop each year. Experiments there are said to have confirmed those made elsewhere as to the beneficial effects of a 5:5:50 Bordeaux mixture. The applications should begin when the plants are a few inches high and should be repeated at intervals of eight or ten days to suit the weather, at the rate of from 50 to 75 gal. per acre according to the size of the plants.

Treatment for late blight of potato, E. Foex (Jour. Agr. Prat., n. ser., 28 (1915), No. 4θ, pp. 438-44θ).—This discussion relates mainly to the experimentation reported by Pethybridge (E. S. R., 32, p. 239) in so far as that deals with the superiority of the Burgundy as compared with the Bordeaux mixture for Phytophthora infestans, or late blight of potatoes.

Wart disease of potatoes (Gard. Chron., 3. ser., 58 (1915), No. 1506, p. 294).—A list is given of varieties of potatoes said to have been recommended by the Board of Agriculture and Fisheries for planting in 1916 on areas infected with wart disease in England and Wales.

The sugar beet nematode and its control, H. B. Shaw (Sugar [Chicago], 17 (1915), Nos. 2, pp. 31-35, figs. 6; 3, pp. 56-60, fig. 1; 4, pp. 58-61; 5, pp. 58-63, figs. 8; 6, pp. 58-62, fig. 1; 7, pp. 55-58; 8, pp. 51-53; 9, pp. 54, 55).—The author

gives results of a study since 1912 of the sugar beet nematode (Heterodera schachtii). The results obtained by others are also freely used, as appearing in the scattered but voluminous European literature covering a period of about 60 years. But little has as yet appeared in English on this subject.

The present distribution of the pest is very extensive, including a large portion of Europe and the Azores. In the United States it has become established in two of the oldest beet districts in California and Utah. It is distributed by tools, the feet, water, and numerous other agencies.

The life history of the nematode is outlined, the brown cyst stage being regarded as very important. Viable eggs and larvæ have been found in these cysts after four or five years, and their contents may withstand a considerable degree of cold, heat, and desiccation. It is thought, however, that a temperature of 63° C. (145.4° F.) for one minute destroys all life in this stage. The life cycle is said to occupy about four to five weeks, so that six or seven generations may be produced in one season. Each female produces from 350 to 400 eggs. The parasite attacks the plants during its larval stage, producing profound changes in their development and product.

Lists are given of plants found to be susceptible or otherwise. Advantage may be taken of this knowledge to starve out the pests by crop rotations which are outlined. Small infested spots may be isolated by trenches filled with lime. Chemical methods, as well as the method of trap plants, have been found to be impracticable in Europe. Exposure of the beet seed to a temperature of 65 to 70° for 5 to 10 minutes not only destroys all nematode life, but apparently stimulates the germinability of the seed. This method is claimed to be extremely simple, inexpensive, and practicable as applied to seeds, and it is recommended that such treatment of imported seed be made general.

A bibliography is given.

Spraying experiments at Ruakura, A. W. Green (Jour. Agr. [New Zeal.], 11 (1915), No. 2, p. 134).—It is stated, in a report of orchard work at Ruakura farm of instruction, that after this season's experiments there is little reason to doubt the value of lime-sulphur solution in this connection. Unsatisfactory results in previous experiments are attributed to the strength of the spray used.

Cedar rust eradication in Berkeley County (Crop Pest Com. W. Va. Bien. Rpt. 1 (1913-14), pp. 33-39, figs. 4).—Besides a discussion of the relations of cedar trees to apple rust as regards control of the latter, an account is given of the concentration of effort in Berkeley County, the practical difficulties encountered in the removal of the cedars, and the results obtained thereby.

The eye rot of the apple, E. S. Salmon and H. Wormald (Gard. Chron., 3. ser., 58 (1915), No. 1506, p. 289, figs. 2).—The authors report having received from growers in Wye, Sussex, and Devonshire apples showing a blossom end rot which may be causally connected with a fungus, apparently a Fusarium, found in some diseased fruits. In one case the diseased apples were densely infested with aphids. The authors recommend as tentative measures for protection the picking and burning of all affected fruit and the use of sprays for the destruction of puncturing insects.

The frog-eye leaf spot of apples, C. H. Crabill (Virginia Sta. Bul. 209 (1915), pp. 16, figs. 6).—According to the author the frog-eye leaf spot is one of the most prevalent foliage diseases of the apple in Virginia, its attacks often causing serious loss. Various fungi have been attributed as causing this disease, but investigations of the author show that the initial infection and enlargement are caused by Sphæropsis malorum. Alternaria mali occurs as

a saprophyte, rapidly spreading through the spot behind the Sphæropsis, and may become a parasite under conditions of excessive moisture. *Phyllosticta pirina*, *P. limitata*, and *Coniothyrium pirinum* occur as saprophytes but are not able to produce enlargements. The light gray color about some frog-eye spots which have ceased to enlarge is said to be due to *P. pirina*. Other fungi reported as a cause of this disease are said to occur only as saprophytes.

A description is given of the relation of the fungus causing Sphæropsis spots to black rot and canker of the apple. Spraying experiments for the control of frog-eye leaf spot were conducted in various parts of Virginia from 1910 to 1914, lime-sulphur solution, Bordeaux mixture, iron Bordeaux mixture, and copper-lime-sulphur being employed. All of these fungicides greatly reduced the amount of injury, lime-sulphur ordinarily being somewhat more efficient than the others.

Dimorphism in Coniothyrium pirinum, C. H. CRABILL (Amer. Jour. Bot., 2 (1915), No. 9, pp. 449-467, figs. 15).—Having dealt in a previous paper (E. S. R., 29, p. 648) with the morphology, cultural features, and host relationships of *C. pirinum*, the author reports the outcome of pure cultures of this fungus isolated from apple leaf spots.

It is stated that *C. pirinum* is sometimes dimorphic in culture and probably also in nature. Two strains have been isolated, a plus strain fruiting abundantly, and a minus strain fruiting poorly which arises in artificial culture by sudden sporting from the plus strain. Minus strains are said to remain constant generation after generation. Attempts to develop the strains from each other by continuous selection of extremes were unsuccessful. The cause of the sporting has not been ascertained,

The gray mold or Botrytis disease of citrus trees, C. C. BRITTLEBANK (Jour. Dept. Agr. Victoria, 13 (1915), No. 10, pp. 605-608, figs. 7).—This disease was noted in portions of Australia in 1900, 1911, 1912, and 1913. The rapid progress observed during the latter years has apparently been checked recently by a protracted drought, but it is thought that the disease occurs now wherever citrus trees are grown in this region.

The life history of the fungus and the progress of the disease are described. The fungus can exist either as a saprophyte or as a wound parasite, reproducing by means of conidia or of sclerotia. Infection is favored by wet weather.

All the smaller infected branches should be cut out and all diseased material scraped from the larger branches and the stem, all the removed material being destroyed by fire and all wounds being painted with a mixture of carbolic acid and water in equal parts. A paste prepared by mixing when cool 1 lb. copper sulphate in 1 gal. water and 2 lbs. of quicklime freshly slaked in ½ gal. water, may be applied to diseased places after cleaning them thoroughly.

The same fungus has recently been found to produce injury or death in case of seedlings of *Eucalyptus citriodora* and *Jacaranda mimosæfolia*.

Citrus canker, F. A. Wolf (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 2. pp. 69-100, pls. 4, figs. 8).—In a paper contributed from the Alabama Experiment Station, the author gives an account of an investigation of the life history of the organism Pseudomonas citri, the cause of the citrus canker. Infection is considered to occur through natural openings and through wounds. The rapid spread of the disease is favored by the simultaneous occurrence of newly exposed cankerous cells and the presence of a film of moisture, especially on young parts of the plant. The bacteria occur for the most part between the cells of the host and cause them to become considerably hypertrophied.

In addition to the bacteria causing this disease, fungi belonging to the genera Phoma, Fusarium, and Glœosporium have been isolated from citrus

cankers. Of these the species of Phoma alone was found to be notably active in the disintegration of the tissues. This fungus is believed to be hitherto undescribed and the name *Phoma socia* n. sp. is given it.

Some investigations are reported in which an attempt was made to determine causes for the difference in susceptibility to citrus canker of Satsuma oranges and grapefruit. As a result of these studies the author concludes that difference in susceptibility can not be accounted for on the basis of differences in the total organic acids in the two plants.

Attention is called to the failure of spray mixtures to control this disease, the successful eradication of which seems to be possible only when the work of destruction of trees is thoroughly done with the observation of proper sanitary precautions.

Panama disease of bananas (Jour. Jamaica Agr. Soc., 18 (1914), No. 12, p. 502; Queensland Agr. Jour., n. ser., 4 (1915), No. 1, pp. 41, 42).—Measures insisted upon to prevent the general spread of Panama disease include a rigid quarantine of infected areas and thorough disinfection of boots, tools, etc., used in connection therewith; complete destruction of diseased material; and fencing all infected areas with close-woven wire to prevent the passage of animals.

A disease of cinnamon, A. Sharples (Agr. Bul. Fed. Malay States, 3 (1915), No. 9, p. 381).—Individual cinnamon bushes growing in the experimental gardens at Kuala Lumpur have been dying for some time. The trouble usually begins with the death of a branch. The whole cortex is diseased, showing the presence of a fungus, Pestalozzia palmarum, the fruiting bodies of which are embedded therein until its disintegration frees the spores. Potato agar cultures show hyphæ in two days, and in four days the black fruiting bodies appear, showing the typical spores. Attack by this fungus is localized and can usually be controlled even when the trees are growing in unfavorable conditions. In Ceylon, P. palmarum causes a gray blight by its attack on the leaves, which is not so serious as the stem attack.

The most effective means of protection is the removal of all diseased portions before the spores are freed from the fruiting bodies in the rotting cortex.

The anthracnose of the mango, J. B. Rober (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 5, pp. 164-171, pl. 1).—Anthracnose (Glæosporium mangiferæ or Colletotrichum glæosporioides), said to be the most common and destructive of mango diseases, and attacking almost every variety wherever grown, is described as damaging the flowers, leaves, and fruit. Bordeaux mixture gave excellent results, especially with the more susceptible varieties.

A few trial shipments indicated that mangoes can be shipped successfully to distant markets in cold storage. Fruits should be full but not ripe when taken from the tree, and this should be done without injuring the fruit. The boxes for shipping and packing should be of medium size, holding about 2 doz. fruits.

A disease of mangosteen trees, W. N. C. Belgrave (Agr. Bul. Fed. Malay States, 3 (1915), No. 6-7, p. 229).—It is stated that mangosteen trees are liable to attack by the fungus Zignoella garciniæ, which causes the formation of cankers in the stems, working back from the younger to the older branches. When these have been ringed by the cankers, the foliage withers, turns brown, and dies, the death of the whole tree quickly following. In cross section, the cankers are seen to extend inward to the wood, but the latter is seldom attacked. Fructification of a species of Hendersonia, possibly another stage of Zignoella, are often found on the cankers.

The most practical measures are to cut and burn the trees which have begun to wilt, as these are doomed, and to remove the affected branches in the vicinity.

Insects and diseases affecting pinks and their treatment, J. Lochot (Jardin, 29 (1915), Nos. 669, pp. 315, 316; 670, p. 322).—This article, besides mentioning some insect pests of pinks, and nematodes, the control of which requires eradication of the plants attacked, discusses also a rust of pinks due to a Puccinia, which is said to yield to treatment with sulphur sprays, and a browning due to Helminthosporium echinulatum, for which is prescribed a 2 per cent copper spray with removal of all parts seriously affected.

Seasonal duration of ascospore expulsion of Endothia parasitica, F. D. Heald and R. A. Studhalter (Amer. Jour. Bot., 2 (1915), No. 9, pp. 429-448, figs. 6).—Describing the method, plan, and results of attempts to ascertain by means of traps the activity of spore expulsion by E. parasitica, the authors state that the expulsion begins in the spring with the first warm rains. It increases to a maximum under favoring conditions, declining under the lower temperatures of autumn, and ceasing entirely during the cooler portions of the year, even under abundant rainfall. During one-half to two-thirds of the year, there is a copious expulsion with each rain of any consequence, except when the temperature drops below the minimum, which is not far from 50 to 55° F.

Perithecial pustules of the chestnut blight fungus show a remarkable power of spore production. This is not exhausted in a single season, being sometimes as marked during the second season as the first. Apparently, also, pustules first producing mature perithecia in the fall may produce spores during the two following seasons. This is due to the fact of successive maturing of asci, successive maturing of perithecia, and successive maturing of stromata throughout the season.

A bibliography is appended.

Report of chestnut blight eradication, A. B. Brooks (Crop Pest Com. W. Va. Bien. Rpt., 1 (1913-14), pp. 50-61, figs. 8).—This is a brief account of work done to eradicate the chestnut blight in portions of West Virginia in 1913-14.

Fire injury to chestnut trees appears to favor greatly attack by the blight fungus. Experimentation was begun to determine to what extent the spread of blight can be checked by cutting the diseased trees and leaving them flat on the ground, based upon the observation that the spread from cankers situated low down on trees is slight as compared with that from those situated high up, especially on trees in prominent situations.

The leaf blotch of horse-chestnut, V. B. Stewart (New York Cornell Sta. Bul. 371 (1916), pp. 411-419, pl. 1, figs. 8).—The author gives a description of the leaf blotch of horse-chestnut and allied species due to the fungus Guignardia asculi. This fungus is said to have caused considerable injury to trees, particularly those in the nursery, through the destruction of the leaf tissue. Experiments for the control of the leaf blotch have shown that lime-sulphur solution or Bordeaux mixture can be effectively employed, but considerable difficulty is experienced in their application owing to the dense foliage of the trees.

In the summer of 1915 an experiment was made on nursery trees for the control of the leaf blotch by dusting a mixture containing 90 parts of finely ground sulphur and 10 parts of powdered arsenate of lead. This treatment was found effective and is preferred, as there is little danger of injuring the foliage by burning. The dust mixture, it is claimed, can be applied more thoroughly and with greater facility than the spraying solutions, but its cost is somewhat higher than either of the solutions above mentioned.

Host plants of pink disease in Malaya, A. Sharples (Agr. Bul. Fed. Malay States, 3 (1915), No. 5, pp. 203, 204).—It is stated that three new hosts are to be added to the list previously published (E. S. R., 33, p. 151). Of these, Tephrosia hookeriana is though to have served as a center of infection in one

place where the number of cases of pink disease had increased greatly during the last year. *Indigofera arrecta* was found to be attacked by pink disease, but mildly and only in a few instances, where the host plants were not in good condition. *Clitoria cajanifolia* has also been recorded as a host for pink disease at the Buitenzorg Botanic Gardens. The form assumed by the fungus on the above plants was the pink incrustation commonly observed on rubber, on which usually, as on all these plants, no trace of basidiospores was found.

The red rot of conifers, F. H. Abbott (Vermont Sta. Bul. 191 (1915), pp. 3-20, pls. 4, figs. 2).—According to the author the so-called red rot of conifers is due to the fungus Trametes pini, which is primarily a parasite assuming more or less the character of a saprophyte when the tree falls. The fungus is said to attack tamarack, pine, hemlock, spruce, and balsam, its ravages being greatest in unthinned stands, especially in pure stands of white pine.

The infection apparently occurs mainly through broken branches which expose the heartwood, root infection being considered doubtful. The principal means of spreading the disease is through the sporophores, which are formed on all host species but vary in form on different hosts, occurring on both standing and fallen trees. The damage to the wood is brought about by the solution of its lignin content by the enzym of the fungus and this injury appears to cease when the tree falls. The damaged wood may be used in the manufacture of boxes, tubs, wooden pails, etc. For prevention of spread of the red rot, proper thinning, removing the diseased trees, and destroying the fruiting bodies are recommended.

The two rust diseases of the spruce, A. W. BORTHWICK and M. WILSON (Notes Roy. Bot. Gard. Edinb., 9 (1915), No. 41, pp. 65-69, pl. 1).—Discussing the life history of Chrysomyxa rhododendri causing spruce blister rust and also rust of rhododendrons, the authors state that although the presence of the spruce is apparently not essential to the continued existence of the fungus, the actidial stage on the spruce can exist only where the rhododendron is present, as the infection of the needles is brought about only by the sporidia. Removal of the rhododendron will, therefore, completely check the disease. The effect of this disease on rhododendron is not very serious. In case of the spruce, the diseased needles fall in the summer of infection, and in severe cases, the trees may be almost stripped of their foliage.

C. abietis, the needle rust of spruce, is also discussed as to its biology and distribution. Certain spruces in a wood may be badly attacked while others remain free from the disease. This is ascribed to the fact that infection takes place in a certain definite stage in the development of the young leaves, which, in some cases, does not coincide with the exact developmental stage of the sporidia necessary to infection. While a considerable degree of defoliation may take place, the disease usually fails to maintain itself through a long series of years on any one tree, so that cutting down the trees on account of this disease is not recommended.

Honey fungus, C. Frömbling (Forstw. Centbl., n. ser., 37 (1915), No. 7, pp. 299-304).—This is a somewhat general summation of observations on Agaricus melleus regarding its activity and effects as related to some conifers in connection with such conditions as age, soil, growth, spacing, and shading by other trees.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

Birds of Porto Rico, A. Wetmore (Porto Rico Bd. Agr. Expt. Sta. Bul. 15 (1916), pp. 140. pls. 10).—This is a reprint, text unchanged, of Bulletin 326 of this Department, previously noted (E. S. R., 34, p. 849).

Winter crow roosts, E. R. KALMBACH (U. S. Dept. Agr. Yearbook 1915, pp. 83-100, pls. 2, flg. 1).—This account of the roosting habit of crows, location of roosts, and estimates of the numbers that gather in certain roosts includes a list which gives the location, by States, of the crow roosts known to have been occupied in the winter of 1911-12, together with estimates of the numbers of birds in each. A discussion of the winter food of crows and their relation to seed distribution is included.

Oklahoma insect calendar, C. E. Sanborn (Oklahoma Sta. Circ. 39 (1916), folio).—This calendar lists 42 types of insects and gives the appearance and parts of plants affected by each type, together with the treatment or suggestions relative to control. Spraying schedules for the apple, peach, cherry, and plum and general insecticide formulas are also given.

Insect injury to cotton seedlings, B. R. Coad and R. W. Howe (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 3, pp. 129-140, pls. 5).—This paper reports observations made in the vicinity of Tallulah, La., during the spring of 1915, on the mutilation of the leaves of cotton seedlings by insects. It appears that this injury can be caused by any of several insects, including a number of species of lepidopterous larvæ, grasshoppers, and leaf beetles. Tussock larvæ were responsible for most of the damage early in the season and then were supplanted by grasshopper nymphs. The other insects mentioned are the "woolly bear" larvæ, or salt marsh caterpillar, and the cutworms Prodenia ornithogalli and Peridroma margaritosa saucia.

Recent grasshopper outbreaks and latest methods of controlling them, F. M. Webster (U. S. Dept. Agr. Yearbook 1915, pp. 263-272, pls. 6, figs. 3).—This is a popular summary prepared by the author just prior to his death (E. S. R., 34, p. 200).

The terrapin scale: An important insect enemy of peach orchards, F. L. SIMANTON (U. S. Dept. Agr. Bul. 351 (1916), pp. 96, pls. 3, figs. 20).—The increasing abundance of the terrapin scale (Eulecanium nigrofasciatum) in the eastern United States, together with numerous complaints recently received from orchardists in many localities within the Appalachian peach belt of severe injury to peaches and of inability to control the pest with the materials commonly used, led to investigations during the seasons of 1912 and 1913 at a field laboratory at Mont Alto, Pa., a locality well within the limits of the badly infested area.

The terrapin scale is a native species which first came to the attention of economic entomologists in 1870, and which since 1898 has gradually assumed more and more importance as an enemy of the peach until now it is feared by the peach growers of Maryland and Pennsylvania more than any other species of scale. At present it is largely confined to the humid area of the Austral Region, considerably more than one-half of all the known infestations being found in Pennsylvania and Maryland.

In its range and importance this scale ranks easily as second among the scale pests of the peach, and while neither so prolific nor so injurious as the San José scale, it is even more of a nuisance owing to the difficulty met with in its control. The injury to the trees from loss of sap, while considerable in badly infested orchards, is small in comparison with the damage resulting from the deposit of honeydew, which on badly infested trees makes the fruit almost unsalable. While it attacks more than 30 species of plants it becomes abundant on only a comparatively few, its preference for its principal food plants being as follows: Peach, plum, maple, cherry, sycamore, and mistletoe.

A detailed report of life history studies is presented, much of which appears in tabular form and in charts. "The female of the terrapin scale reaches maturity about the first of June and gives birth to living young soon after-

wards. These are retained for a period of from one to three days in the brood chamber, which is a dome-shaped cavity beneath the scale. They then emerge and migrate at once to the underside of the leaves, where they settle, mostly along the midrib and the larger veins. The first instar, which lasts about 18 days, is vegetative and the larvæ show no sexual differentiation, but during the second instar, which also lasts about 18 days, sexual differentiation is very pronounced. At the end of this instar the female is very flat and circular, while the male, which is flat and decidedly oval, is protected by a conspicuous waxy structure called the puparium. After the second instar the sexes follow entirely different lines of development.

"The female remains for one day upon the leaves after entering the third instar, which is the final instar for this sex. During this day it secretes a thin wax scale, which protects it during the twigward migration. At the beginning of this migration the female larvæ abandon the leaves and pass to the basal part of the new growth, where they make their final attachment within the area of greatest illumination. They then commence a period of rapid growth, during the first 11 days of which they develop their mating color, which is a conspicuous red band upon the middorsal line. At the time the dorsal band is completed the male migrates to the leaves, mates, and dies. The female after mating starts a rapid growth, during which the mating colors and the larval characters are lost and during which vast quantities of honeydew are deposited. By the end of the twentieth day upon the twig the female has assumed all the adult characters. After this, growth gradually slackens until the cold of the approaching winter forces the scale into hibernation. In the spring growth is resumed. Maturity is reached early in June and the scale dies early in July, after having lived about 13 months.

"The male, which makes the second molt and passes all of its remaining instars except the last day of the imago under the protection of the puparium, loses its mouth parts at this time and lives during the remainder of its life upon nourishment taken in the first two instars. The third or prepupal instar lasts about two days and is a period of rapid metamorphosis, in which the larval organs are replaced by the adult structures. In the fourth or pupal instar, which lasts for about eight days, the adult organs reach their full development. At the fourth and final molt the imago escapes from the pupal case but remains for about two days under the puparium before emerging, when it migrates at once to the twigs, copulates, and then dies, after having lived about 49 days."

Mention is made of four attending ants, none of which benefit the scale to any extent, of several predaceous enemies, and of a number of parasites. The scale is heavily parasitized by *Coccophagus lecanii*, which was the most abundant species reared in 1912, although *C. cognatus* was also abundant, especially in the fall. In 1913 *C. lecanii* was rare, while *C. cognatus* appeared in large numbers and attacked the developing females in the spring, killing from 20 to 50 per cent of the scales. *Aphycus stomachosus* was the most abundant parasite in 1913, being more numerous than *C. cognatus*.

Remedial work conducted during the first season was directed toward the direct prevention of soot injury, which was found to be impractical. In the second season sprayings were directed against the scale, seven groups of materials being tested. The first of these groups contained corn oil, rosin oil, and gasoline, the two first named being very good treatments but injurious to the trees, while gasoline was inefficient but gave promise as a wax solvent and penetrant. The second group contained miscible oils which were found to be injurious when used in the winter at effective strengths but were used without injury when applied in the spring before the swelling and the bursting of the fruit

buds. It was found that healthy 11-year-old trees could be sprayed for three consecutive seasons with miscible oil, 1:18, without injury to the trees, and that the scale could be controlled by two seasons' sprayings with this oil. It was further found that combining gasoline emulsion and miscible oil added to the efficiency of the oil. The greatest efficiency was obtained when 5 parts of miscible oil were added to 2 parts of gasoline (emulsified) and 92 parts of water. The third group consisted of ten experiments made with cotton-seed oil and combinations with gasoline. The highest efficiency was obtained by using an emulsion containing cotton-seed oil 5 gal., gasoline 3 gal., soap 2 lbs., and water 92 gal. The fourth group consisting of five experiments made with raw linseed oil gave promising results, the oil being very efficient alone as a 10 per cent emulsion and even more so when combined with gasoline. The gasoline component increases the fluidity of the oil, dissolves the protecting wax film, and tends to asphyxiate the scales. The best results were obtained by using an emulsion made up of raw linseed oil 5 gal., gasoline 3 gal., laundry soap 2 lbs., and water 92 gal. This emulsion applied in the spring before the buds burst will control the terrapin scale at a single application, at a cost for material of from 1 to 8 cts. per tree. This was found to be the most effective treatment of any of the remedies tried against this insect. Group 5, consisting of two experiments with mixed oils, showed no advantages in mixing linseed and cotton-seed oils. In group 6 nicotin was tested in 14 experiments, proving this substance to be inefficient. Group 7, consisting of 20 experiments with various coating sprays, gave ineffective results.

In making recommendations for control the author advises the application of the linseed-gasoline emulsion above mentioned, applied in the spring before the buds burst. In order to protect the crop after the trees are in foliage, it is recommended that an application be made, just before the leafward migration, of the formula consisting of flour (in paste) 10 lbs., stone lime 15 lbs., sulphur 20 lbs., and water to make 50 gal.

A 4-page bibliography is included.

The alfalfa webworm, C. E. Sanborn (Oklahoma Sta. Bul. 109 (1916), pp. 3-7, figs. 4).—Loxostege similatis, which occurs throughout the United States and in South America, passes the winter in Oklahoma in the pupal stage. The adults emerge from these pupal forms and appear about the middle of April. The second generation appears about May 25, the third from June 28 to July 16, the fourth from July 27 to August 2, the fifth about September 16, and adult forms are present as late as November. The adults deposit eggs in masses, generally on the lower side of the leaves of their food plants, each mass containing from 5 to 42 eggs, or an average of 19, which hatch ordinarily within three or four days. The larvæ or webworms develop in about three weeks, and the pupal period during summer is ordinarily seven or eight days, but in hibernation extends from about the middle of October to the middle of April.

All broods, except the last or fall brood, are characterized by their web-spinning habit. While the "careless" or pigweed is its natural food plant, it feeds on practically all the common weeds, except the jimson weed and devil's claw. The methods of control mentioned are mowing infested fields, poisoning fields, renovation, clean culture, and jarring cultivated plants such as corn and cotton.

A list of 21 references is appended.

A general survey of the May beetles (Phyllophaga) of Illinois, S. A. Forbes (Illinois Sta. Bul. 186 (1916), pp. 215-257, fig. 1).—The data here presented relate to a study of the number of species and specimens, dates of occurrence, food plants, and distribution in Illinois of nearly 119,000 May beetles or June

bugs, belonging to 34 species of the genus Phyllophaga and collected in 42 counties from 1905 to 1911, inclusive, and in 1913.

"Thirty-four species of May beetles are recognized in Illinois. They vary greatly in abundance, the above collection containing but two specimens of the rarest species and 43,349 of the commonest. Ninety-one per cent of the specimens collected belonged to 10 of the species, the other 9 per cent being distributed among the 24 species remaining.

"A detailed discussion of the species, taken separately, shows for each its numbers in each year and in each of the three sections of the State, the dates in each year of its first appearance and its greatest abundance, and its comparative numbers on each of its food plants. By means of the data of numbers and distribution, the dominant and subdominant species are distinguished for each year and district, and the intervals between their periods of greatest abundance are considered with reference to the length of the life cycle of the species concerned.

"From a comparison of the May beetles derived from northern, central, and southern Illinois, respectively, it appears that three species are practically limited to northern Illinois, three to the northern and central parts of the State, two to the central and southern, and 11 to southern Illinois. The actual boundary lines between these areas of distribution are, however, irregular and meandering, especially that between southern and central Illinois, which is influenced by the course of the streams, the southern species following them northward toward their headwaters in a way to bring several such species far into the central division of the State.

"The seasonal succession of the species—that is, the order in which they make their first appearance in spring—is worked out for each section of the State as carefully as the wide distribution and irregular time limits of the collections will permit.

"Generally speaking, successive periods of extraordinary abundance of a species in any locality or district show little correspondence to any possible life cycle, being too various and irregular for that interpretation. Extensive parasitism of imagos and larvæ by insects, annelids, Protozoa, and fungi produces widespread and destructive epidemic diseases, a knowledge of whose prevalence and status is essential to any safe prediction of periods of destructive abundance of the white grubs.

"The May beetle species known as *Phyllophaga fusca* and *P. futilis* were evidently those which produced most of the white grubs which were so abundant in northern Illinois in 1912 as to do heavy damage to farm crops in several counties. Two-thirds of the collections made in that section in 1914 were of these species, the first of the two mentioned being, however, nearly four times as abundant as the second.

"The facts concerning the food plants of the more abundant species are grouped and classified in a way to distinguish trees and shrubs especially attractive to them, and consequently dangerous to adjacent crops by reason of the abundance of white grubs to descend from them."

The influence of trees and crops on injury by white grubs, S. A. FORBES (Illinois Sta. Bul. 187 (1916), pp. 261-265).—The natural supposition that fields nearest to the food plants of May beetles, that is trees, must become most heavily stocked with eggs and consequently worst injured by grubs when these eggs are hatched led the author in 1904 to commence the collection of information bearing on the subject.

Collections were made of white grubs in fields that were being plowed in the fall or spring by walking behind the plowman and making note of the distance traveled in each field and the number of grubs exposed by the plow, and recording at the same time the distance from the field to the nearest trees upon which the May beetles might be supposed to have fed. Observations and collections of this nature were made by six field assistants during 1904, 1905, 1907, and 1908 in 549 fields widely scattered throughout central Illinois, and in a few fields also in the northern and southern parts of the State. The total distance traveled was over 429 miles, a total of 12,069 grubs of the genus Phyllophaga and 1,187 of the genus Cyclocephala being collected.

For the purpose of classification all of the data thus obtained were assorted into four groups, according to the distance of the fields from the nearest trees. In group 1, in which 224 miles were traveled in fields with trees within or on their borders or within less than one-eighth of a mile, white grubs of the genus Phyllophaga were found at an average rate of 39.17 to the mile. In group 2, 40 miles were traveled in fields with trees more than one-eighth but less than one-fourth of a mile away, and in these Phyllophaga grubs averaged 17.83 to the mile. In group 3, in fields with trees more than one-quarter of a mile away and less than one-half mile, 130 miles were traveled and Phyllophaga grubs averaged 15.94 to the mile. In group 4, in fields with trees half a mile away or more, 35 miles were traveled and 14.4 was found as the average number of Phyllophaga grubs.

In a study of the data bearing on the kind of crops in which May beetles prefer to lay their eggs, it was found "that more eggs were laid in pastures (84 grubs per mile) than in any other crop; that small grain came next with 61 and 62 per mile for fields which had been in oats and wheat, respectively; that fallow land, grown up of course to weeds, largely grasses, was third, with 48 grubs to the mile; that clover and corn seemed not far apart in attractiveness to the egg-laying beetles—clover with 30 and corn with 25 grubs to the mile; and that meadow crops (excluding clover) were least sought by the egg-laying beetles—about 15 grubs to the mile in fields which had been in such crops when the eggs were laid. . . . The evidence of the predominance of grasses and small grains over corn and other crops as a lure to May beetles about to lay their eggs is unmistakable here, and much more emphatic than that obtained from our general collections behind the plow."

Studies of the Mexican cotton-boll weevil in the Mississippi Valley, R. W. Howe (U. S. Dept. Agr. Bul. 358 (1916), pp. 32, figs. 2).—This is a report of studies carried on during 1913, 1914, and 1915, largely at the Delta Boll Weevil Laboratory at Tallulah, La., with a view to determining what influence new climatic and environmental conditions have upon the biology of the boll weevil. The work has been summarized by the author as follows:

"In northern Louisiana the average longevity of the boll weevil adults on cotton squares was 54.56 days, on bolls 31.41 days, on cotton leaves 8.17, and on okra fruit 5.4, the average for these different classes of foods being 14.13 days. The females live somewhat longer than the males, there being an average of 12.5 days for females and 9.82 for males.

"A number of weevils were found feeding in okra blooms in the field, but attempts to cause them to breed in okra fruit in the laboratory were unsuccessful. A number of eggs were deposited, but they failed to hatch.

"The largest number of eggs deposited by the first generation weevils was 204, the average being 132. The daily maximum varied from 5 to 12. Second generation weevils showed somewhat less fecundity, the maximum oviposition being 175 eggs and the average 69.4. The average period of oviposition was 38.2 days, the range being 1 to 77 days. The greatest activity of the weevil in depositing eggs was found to be between the hours of 9 a. m. and 1 p. m., but

certain numbers of eggs were deposited at all times of the day and during the night. The average period from oviposition to the emergence of the adult was practically 14 days for each of the five generations.

"Seven complete generations were developed at Tallulah during the season." Boll weevil in Alabama, W. E. Hinds (Alabama Col. Sta. Bul. 188 (1916), pp. 23-64, pls. 4, figs. 3).—This general account deals with the spread of the boll weevil in Alabama, describes and illustrates the stages and work of the weevil, and discusses the means of spread, propagation, hibernation, and control measures.

Oviposition of Megastigmus spermotrophus in the seed of Douglas fir, J. M. Miller (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 2, pp. 65-68, pls. 3).—This account of the oviposition of the seed chalcidid M. spermotrophus is based upon observations made at the Forest Insect Station of the Bureau of Entomology of this Department at Ashland, Oreg., largely during the season of 1915.

During the season of 1914 male adults began to emerge on April 12 and the females on April 16 from stored Douglas fir seed kept in a rearing box; 2.897 adults emerged from 6.75 oz. of seed, the period of maximum emergence occurring between April 23 and May 11. In 1915 the maximum period of emergence in the laboratory occurred between April 20 and May 2. From cones which were kept caged over winter under outdoor conditions at the same elevation, the maximum emergence occurred between May 1 and 16. At elevations of 3,000 to 4,000 ft., the emergence occurred during the latter part of May, and above 4,000 ft. much of the emergence occurred in June.

The oviposition of two females was recorded on April 22 and that of the same number on April 23, and females were observed ovipositing from this time up until May 5. From two to five minutes were required for oviposition, the same female having been observed to oviposit five times on the same cone. Actual oviposition in the field was observed only once and that on May 28, by J. E. Patterson.

Life history and habits of two new nematodes parasitic on insects, J. H. MERRILL and A. L. FORD (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 3, pp. 115-127, figs. 3).—Two new nematodes have been observed at the Kansas Experiment Station, one parasitic on the elm borer and the other on the termite Leucotermes lucifugus. When 121 beetles obtained from a single elm tree were kept in breeding cages in no instance were eggs deposited and both sexes eventually weakened and died, examinations showing death to have been due to nematode parasitization. Several colonies of L. lucifugus were examined and 76.92 per cent found parasitized by nematodes.

Specimens of these nematodes were submitted to N. A. Cobb of this Department, who describes the species which parasitized the elm borer under the name *Diplogaster labita* n. sp., and that of the termite under the name *D. aerivora*, n. sp.

"The eggs of *D. labiata* hatched in from 30 to 32 hours, while those of *D. aerivora* hatched in about 18 hours. The eggs of *D. labiata* were deposited singly, while those of *D. aerivora* were deposited in groups. More cases of eggs hatching in the body were found in *D. aerivora* than in *D. labiata*. The eggs of both species developed similarly.

"Both species, when reared in water cultures, used the same food, but in nature they had different hosts. Both species molted, but the process differed in that *D. labiata* fastened its posterior end, while *D. aerivora* did not. The adults of *D. aerivora* were larger than those of *D. labiata* and required much less time to mature. In water cultures the females of both species were more

numerous than the males. Although mating was similar in both species, **D**. *labiata* required more time for the process. Individuals of **D**. *labiata* usually mated but once, while those of **D**. *aerivora* mated repeatedly. Neither species in their habits showed any preference to day or night. The females of **D**. *aerivora* had a period of oviposition of about 13 days, while in **D**. *labiata* this period lasted only about two days.

"In both species adaptable and plentiful food acted as a stimulant to reproduction. Both species attacked insects, but in different regions of the body, as *D. aerivora* was found in the head while *D. labiata* was found in the intestines. The life cycle of *D. labiata* required more than twice as much time as did that of *D. aerivora*. *D. aerivora* was successfully introduced into the termites."

FOODS-HUMAN NUTRITION.

[Progress in] physiological chemistry [during 1915], F. G. HOPKINS (Ann. Rpts. Prog. Chem. [London], 12 (1915), pp. 187-209).—The author reviews and discusses important contributions by a number of investigators to the knowledge of various phases of physiological chemistry, including general metabolism (especially the basal metabolism of men and women, the surface law, and the specific dynamic action of food); the chemistry of proteins (especially some aspects of protein metabolism); carbohydrate and fat metabolism; growth-stimulating substances; and internal secretions. The bulk of the material has been noted from the original sources.

Shipping fish 3,000 miles to market, E. D. CLARK (U. S. Dept. Agr. Year-book 1915, pp. 155-158, pls. 3).—Information is given regarding the methods of handling, storing, and shipping halibut and salmon from the Pacific coast to-markets all over the country.

An outbreak of typhoid attributed to infected oysters, P. B. Brooks (Jour. Amer. Med. Assoc., 66 (1916), No. 19, pp. 1445-1447).—About 50 cases of typhoid fever in the city of Binghamton, N. Y., and near-by municipalities were apparently traced to oysters supplied by two wholesale dealers.

The baking qualities of different varieties of wheat, O. RAMMSTEDT (Ztschr. Öffentl. Chem., 21 (1915), Nos. 20, pp. 306-312; 21, pp. 321-329; 22, pp. 337-345).—Analytical data and the results of baking tests are reported, showing the relationship between the chemical composition of several different grades of wheat and the volume of the resulting loaf.

Nutritive value of wheat flour and bread in relation to phosphorus content, G. Masoni (Staz. Sper. Agr. Ital., 48 (1915), No. 5-7, pp. 385-456).—A large amount of analytical data is given showing the phosphorus content of different grades of wheat flour and the resulting bread. In general it is indicated that the percentage of mineral substances, organic phosphorus, and ether extract increases from flour to bran. Practically the same amounts of phytin and nuclein occur in the bread as in the flour, but, probably owing to the low temperature at which it is decomposed, lecithin occurs in lesser amounts in breadd.

The author concludes that the coarser flours have a greater nutritive value than the finer and whiter flours, since they contain larger percentages of phosphorus and nitrogenous compounds, complex mineral substances, and crude fat.

A bibliography is appended.

Does light influence the staling of bread? J. R. Katz (Hoppe-Seyler's Ztschr. Physiol. Chem., 96 (1916), No. 4-5, pp. 288-291).—From a comparative examination of samples of bread kept in a dark room and exposed to both

direct and diffused sunlight, the author concludes that light does not influence the staling of bread.

Previous studies of the staling of bread have been noted (E. S. R., 34, p. 858). The noteworthy property of aldehydes in retarding the staling of bread, J. R. Katz (Hoppe-Seyler's Ztschr. Physiol. Chem., 96 (1916), No. 4-5, pp. 314-322).—Experimental data are reported regarding the influence of aldehydes and ketones on the staling of bread. It was found that aldehydes act on the starch granules, thereby keeping bread fresh for an exceptionally long time. Ketones did not possess this property.

Bread making and butyric ferment in Latium, R. Perotti and U. Cristo-foletti (Staz. Sper. Agr. Ital., 48 (1915), No. 5-7, pp. 361-384).—The authors report a study of the ordinary leaven of Velletri bread, from which Clostridium butyrium and Saccharomyces minor were isolated. The good qualities of this bread are considered to be due largely to butyric fermentation.

Seaweed as a supplementary food material, E. Beckmann (Abs. in Zentbl. Biochem. u. Biophys., 18 (1915), No. 11, p. 379).—Feeding experiments are described in which laboratory animals (dogs and hens) were given bread made from mixtures of finely ground seaweed and wheat, rye, and potato flours. During baking the characteristic odor disappeared, and the bread was found to possess good properties. Analytical data are given.

The effects of commercial glucose when fed to white rats, A. J. Carlson, L. Hektoen, and E. R. LeCount (Jour. Amer. Chem. Soc., 38 (1916), No. 4, pp. 930-936, fig. 1).—The experiments here reported cover a period of six months, and were carried out to study the general effects of commercial glucose when consumed regularly in considerable quantities. Laboratory animals (white rats) were fed upon bread containing the glucose. As controls, other rats were fed on bread containing granulated cane sugar and others on bread without sugar or glucose. The bread was unleavened and consisted of flour, 1,000 parts; lard, 25 parts; baking soda, 15 parts; hydrochloric acid, enough to neutralize the soda; water as required for the flour, about 655 parts; commercial glucose, 34 parts, in the case of "glucose bread," and granulated cane sugar, 26.5 parts, in the case of "cane sugar bread." The results of the experiments are discussed somewhat at length and the following conclusions are drawn:

"The addition of commercial glucose in the amounts of about 2.5 gm. to 3.5 gm. per kilo of body weight per day to the diet of white rats for a period of six months has no abnormal influence on the animals, either favorable or unfavorable, as determined by the rate of growth fecundity, immunity reactions, and the condition of the organs.

"As both the glucose-fed and the control groups of rats were kept on a liberal diet throughout the observation period, the experiment does not show to what extent the commercial glucose was actually absorbed and oxidized, but in the quantities fed the commercial glucose certainly has no injurious effects."

Gelatin as a food for the people, E. Homberger (Sci. Amer. Sup., 81 (1916), No. 2097, p. 167).—Historical data are given regarding the use and food value of gelatin and the work of recent investigators is summarized briefly. It is stated that gelatin is dissolved very quickly and completely in the cells and by its solution saves the albumin from solution. This quality of saving the albumin is twice as great as that of fats or carbohydrates.

"If, besides gelatin, a certain amount of albumin is supplied to the body, and a certain amount of fats and carbohydrates to prevent the loss of fat, the normal condition of the body can be maintained."

A ferment in water which produces the dehydration of glycerin, E. Volsenet (Ann. Inst. Pasteur, 28 (1914), No. 8, pp. 807-818, figs. 2).—Studies

are reported of an organism thought to be identical with *Bacillus amaracrylus*, which is sometimes contained in water and which is able to dehydrate glycerin with the formation of acrolein.

Chemical determination of the nutritive value of wood and straw, E. Beck-Mann (Abs. in Zentbl. Biochem. u. Biophys., 18 (1915), No. 11, p. 379).—Chemical analyses are reported indicating the following percentages of starch in different kinds of wood cut during the autumn: Birch, 0.95; alder, 1.54; maple, 2.65; and elm, 5.9. In the spring of the year the birch was found to contain 3.67 per cent of starch and 2.44 per cent of ether extract. The amount of ether extract contained in the woods during the autumn varied from 0.37 to 1.35 per cent.

The bacteria in ice cream, W. M. ESTEN and CHRISTIE J. MASON (Connecticut Storrs Sta. Bul. 83 (1915), pp. 128-134, fig. 1).—This investigation was made to determine the effect of storing frozen ice cream on the numbers and kinds of bacteria present. Different grades of cream were used in order to determine the effect of a low or a high initial content of bacteria on the bacterial content of the resulting product. Examinations were generally made of the cream before and after mixing it with the ingredients and of the product just after freezing, and then at intervals of twice a week for a month. Ordinary household methods of freezing were used and the cream was packed in quart bricks which were wrapped in paper, enclosed in pasteboard boxes, and packed in an ice-salt mixture, the latter being renewed as often as necessary to keep the cream solid. No exact temperature measurements were kept. Plate cultures were made of litmus lactose gelatin and these were incubated at 21° C. for seven days and then counted. A table is given which shows the total number of bacteria present, the number of acid-forming organisms, and the number of liquefying bacteria present in the different samples examined.

A few samples of ice cream purchased at retail stores in pint paraffin paper carriers were packed in ice and salt and kept for two or three days before bacteriological examinations were made by the methods used in the above tests. The results of the examinations of the retail samples are reported in tabular form and correspond closely to the results obtained by other investigators in various studies.

The authors conclude that "when ice cream is kept frozen for periods of at least a month there is no marked increase or decrease in the bacterial content as shown by litmus lactose gelatin plate cultures. The percentages of acid bacteria and of liquefying bacteria also remained fairly constant. The source of most of the bacteria is the cream used."

Tomato ketchups, C. H. LaWall and L. Forman (*Penn. Dept. Agr. Bul.* 272 (1915), pp. 30).—This bulletin reports the results of the chemical analysis of 142 samples of tomato ketchups and compares them with a similar investigation made in 1904.

The authors state that great improvement has occurred in the quality of tomato ketchups on the market in the matter of the use of chemical preservatives. The use of artificial coloration has entirely disappeared, and there is no basis in fact for the allegation of the use of injurious amounts of acids and spices in brands containing no sodium benzoate. Information on the 142 samples examined showed no use of unsound materials. Less than 2 per cent of them were illegal, and saccharin was not found to be present in any of those examined.

[Food and drug inspection], R. B. FITZ-RANDOLPH and W. G. TICE (Ann. Rpt. Bd. Health N. J., 38 (1914), pp. 133-183, pl. 1).—The food and drug inspection work of the board during the year ended October 31, 1914, is reported. In

addition to general information regarding the scope of the work, detailed statements are made of the inspection of slaughterhouses, cold-storage plants, canning factories, etc. During the year 6,180 samples of foods and drugs were examined, of which 16.3 per cent were found to be below the legal standard.

An extended report is given of the work done in the sanitary inspection of the shellfish industry of the State.

The use of box rations by the French troops, E. MAUREI. (Bul. Acad. Med. [Paris], 75 (1916), No. 9, pp. 254-259).—Box rations for army use are suggested which contain a mixture of meat and either fresh or dried vegetables chopped in small pieces. It is intended that each box shall furnish about 30 gm. of protein and 500 calories of energy and that each man shall receive 4 of these boxes, the total weight of which shall not exceed 1 kg. To complete the ration, it is recommended that the men receive 1,200 gm. of bread, 0.5 liter of wine, and 100 gm, of dried fruit (preferably figs) every two days. The total energy value of this ration is 3,000 calories daily.

The chemistry of cow's milk and other products used in infant feeding, F. W. Howe (Arch. Ped., 33 (1916), No. 1, pp. 1-12).—A compilation of data showing the composition of milk as affected by a number of different factors, and also the nature and composition of other products (protein milk, whey, etc.) used in infant feeding.

The digestibility of the proteins of milk and their rôle in infant nutrition, L. E. Holt (Arch. Ped., 33 (1916), No. 1, pp. 13-19, flg. 1).—The protein need of infants is considered in the light of recent investigations and clinical experience. The author states that "the digestion of the protein of cow's milk is a much easier matter than was formerly supposed; that while injury may without question be done by high protein feeding, this is very unlikely to occur, unless amounts much in excess of those commonly used in infant feeding are administered; that in such amounts we have as yet neither clinical nor laboratory evidence to show that protein is harmful; that although an infant receiving breastmilk takes rather less than 7 per cent of his calories as protein, this can not be taken as an exact criterion of how much protein should be administered when cow's milk is the food; [and] that the deficiency of cow's milk casein in certain essential amino acids may be made up by giving an excess of this protein."

Present opinion as to the rôle of fat in infant feeding, J. L. Morse (Arch. Ped., 33 (1916), No. 1, pp. 20-24).—A summary and digest of data.

A brief résumé of the rôle of carbohydrates in infant feeding, H. R. Mix-SELL (Arch. Ped., 33 (1916), No. 1, pp. 31-36).—A summary and digest of data. The rôle of salts in infant feeding, F. H. Bartlett (Arch. Ped., 33 (1916),

No. 1, pp. 25-30).—This lecture brings together the results of recent investigations of mineral elements in infant metabolism. Especial attention is given to their relation to the low iron content of cow's and woman's milk; to rickets; to gain in body weight; and to the metabolism of protein, carbohydrate, and fats.

Protein metabolism, J. J. R. MacLeon (Jour. Lab. and Clin. Med., 1 (1915). No. 2, pp. 112-119).—A summary and digest of data with relation to the utilization of free amino acids.

Recuperation.—Nitrogen metabolism of a man when ingesting successively a nonprotein and normal diet after a 7-day fast, F. D. Zeman, J. Kohn, and P. E. Howe (Amer. Jour. Physiol., 36 (1915), No. 4, Proc. Amer. Physiol. Soc., 27 (1914), pp. 362, 363).—In these experiments the authors determined the urinary nitrogen compounds and changes in body weight occurring after a fast in a 4-day recuperation period on a non-protein diet, and in a 4-day final period on a normal diet.

An increase in body weight accompanied by a loss of nitrogen occurred during the nonprotein feeding period, while the reverse was true in the final period. The initial increase in weight after the fast is thought to have resulted from the retention of water and non-nitrogenous food substances.

What is a vitamin? (Jour. Amer. Med. Assoc., 66 (1916), No. 19, p. 1470).—The work of a number of investigators on this subject is discussed briefly.

Fat assimilation, W. R. Bloor (Jour. Biol. Chem., 24 (1916), No. 4, pp. 447-460).—In continuation of previous investigations (E. S. R., 34, pp. 562, 563), feeding experiments with laboratory animals (dogs) are reported, in which determinations of total fat, lecithin, and cholesterol were made in whole blood and plasma during the periods of fat absorption. The results of the experiments are summarized as follows:

"Total fatty acids increase in both plasma and corpuscles but the increase is generally more marked in the corpuscles. Lecithin increases greatly in the corpuscles but only slightly in the plasma. No definite changes in the quantity of cholesterol were noted. A fairly constant relationship between total fatty acids and lecithin was noted in whole blood and corpuscles."

It is concluded that "the blood corpuscles take up the fat from the plasma and transform it into lecithin; that most if not all of the absorbed fat is so transformed; and, therefore, that lecithin is an intermediate step in the metabolism of the fats."

Goat's milk to get test (Mod. Hosp., 6 (1916), No. 3. pp. 232, 233).—Announcement is made of an investigation to be conducted at a New York hospital to determine the value of goat's milk for tuberculosis patients.

It is stated that although goats are particularly immune to tuberculosis and while tubercle bacilli have never been found in the milk, it has not yet been determined whether goat's milk carries with it any protection against tuberculosis. Use has been made of the milk for some time in treating summer diseases of children, and in this respect also the cause of its efficacy is unknown. Analyses have shown that the milk contains about 6 per cent of milk fat, and some investigators have thought that the small size of the fat globule may be the reason for tolerance for the milk in cases of summer complaint.

The dietary factors operating in the production of polyneuritis, E. V. McCollum and Cornella Kennedy (Jour. Biol. Chem., 24 (1916), No. 4, pp. 491–502).—In this investigation the authors studied the relation to polyneuritis of two classes of unknown substances concerned in inducing growth—fat-soluble A, which is soluble in fat and is contained in certain fats, and water-soluble B, which is soluble in water and alcohol and is widely distributed in the animal and vegetable world. By means of experiments with birds the effects of feeding a number of substances were studied. Among them were polished rice with butter fat and with the alcoholic extracts of fat-free wheat embryo; potato juice; cabbage juice; oat extract; and the acetone, benzene, and ethyl acetate extracts of fat-free wheat embryo.

From these experiments the authors concluded that "judging from the appearance of serious nutritional disturbances ending in death which result from a shortage of the fat-soluble A, and the emaciation, weakness, and death which follow restriction to a diet inadequate in its content of the water-soluble B, it seems certain that both these classes of unknown dietary constituents are essential for maintenance as well as for growth. . . .

"In the production of polyneuritis in birds by exclusive rice feeding or exclusive feeding of a ration made up of purified foodstuffs, the degeneration of the nerve cells is the specific result of a lack of the water-soluble B. The fat-soluble A appears to be dispensable, when maintenance alone is involved, for a somewhat longer period than is the factor B."

This last assertion is based upon the fact that polyneuritis in pigeons could be produced by feeding a diet free from both the essential factors A and B, but the birds could be completely cured and maintained in a normal condition for at least 35 days on this same diet by the addition of the water extract of a foodstuff (rolled oats) on which rats can not grow without the addition of butter fat. Other confirmatory evidence is the success obtained in inducing relief from polyneuritis in birds by treatment with lipoid-free water extract of wheat embryo and with such substances as cabbage or potato juice, both of which are practically free from lipoids.

Researches on deficiency diseases.—Experimental beri-beri produced by exclusive feeding of either decorticated or sterilized barley, E. Weill and G. Mouriquand (Compt. Rend. Soc. Biol. [Paris], 78 (1915), No. 19, pp. 649-651).—Experimental beri-beri was produced in pigeons by feeding either decorticated or sterilized barley.

ANIMAL PRODUCTION.

Text-book of animal production, G. Pusch, edited by J. Hansen (Lehrbuch der Allgemeinen Tierzucht. Stuttgart: Ferdinand Enke, 1915, 3. ed., rev. and enl., pp. XXII+547, figs. 222).—This is the third edition of this work, revised and enlarged (E. S. R., 26, p. 573).

The behavior of the accessory chromosomes and of the chromatoid body in the spermatogenesis of the rabbit, L. J. Bachhuber (Biol. Bul. Mar. Biol. Lab. Woods Hole, 30 (1916), No. 4, pp. 294-310, pls. 3).—The author finds from his studies with rabbits that the number of chromosomes in the spermatogonium is probably twenty-two. The number in the primary spermatocytes is placed at twelve and in the secondary spermatocytes at eleven. Two accessory elements, an X and a Y, are present, one-half of the spermatozoa containing the X and the other half the Y element. A chromatoid body is present, but its function was undetermined. It underwent no division and was finally cast off with the excess cytoplasm in the metamorphosing spermatid.

Improvement and management of native pastures in the West, J. T. Jardine (U. S. Dept. Agr. Yearbook 1915, pp. 299-310, pls. 4).—The author reviews the work of the Forest Service in improving the native pasture lands on the National Forests and gives suggestions for improving and managing native pastures, based on the principle of the "deferred" system of grazing, previously referred to (E. S. R., 32, p. 227).

The rate of liberation of hydrocyanic acid from commercial kinds of linseed, S. H. Collins and H. Blair (Chem. News, 111 (1915), No. 2876, pp. 19, 20).—Analyses of a large number of samples of flaxseed show that seeds of oriental origin and from dry, hot climates are all high in total hydrocyanic acid and rich in enzymic activity. The result of changing seed from dry, hot climates to damp and cool conditions is to reduce the amount of hydrocyanic acid evolved by 20±3 per cent and the rate of evolution by 24±5 per cent. Thus it appears that seed grown in temperate climates is a safer cattle feed than that from hotter climates. There is a tendency for seeds originated in temperate climates to give the best yield per acre and to contain the least proportions of cyanogenetic glucosids.

Seaweed as a supplementary feeding material, E. BECKMAN (Sitzber. K. Preuss. Akad. Wiss., 1915, XL, p. 645; abs. in Hyg. Rundschau, 26 (1916), No. 3, p. 85).—An analysis of seaweed is given as follows: Protein from 5 to 6 percent; fat from 0.9 to 2.2; starch from 8.4 to 13.9; crude fiber from 5.4 to 6.4; ash from 18.3 to 23.4; and potassium chlorid from 2.5 to 6.3 per cent. The material is found desirable as a supplementary feed for poultry, growing swine and horses.

Food value of brewers' grains, residue, and yeast, W. Völtz, N. Muhr, A. Baumann, and W. Drauzburg (Landw. Jahrb., 47 (1914), No. 5, pp. 639–671).—In feeding experiments with sheep it was found that brewers' grains containing 90 per cent of dry matter contained 8.5 per cent of digestible protein, 30.4 per cent of digestible nitrogen-free extract, a starch value of 24.8 per cent, and a physiological utility value estimated at 30 per cent of the total energy content. The brewery residue contained 26.7 per cent of digestible protein, 22.4 per cent of digestible nitrogen-free extract, a starch value of 38.7 per cent, and a physiological utility value of 40 per cent of the total energy value. With swine the brewery residue contained 25 per cent of digestible protein and 29.5 per cent of digestible nitrogen-free extract.

Cooperative live stock shipping associations, S. W. Doty and L. D. Hall (U. S. Dept. Agr., Farmers' Bul. 718 (1916), pp. 16, figs. 3).—This publication treats of the origin and extent of the cooperative live stock shipping association movement, the advantages of such associations, and the method of organization.

It is stated that wherever these associations have been formed an appreciable saving to the farmer has resulted. "The profit that formerly went to the local shipper now goes to the farmer, and he has the satisfaction of knowing that he will receive for his stock the actual market price, less the cost of marketing. Moreover, the activities of a competent manager and the influence of a successful association make for a general improvement in methods of marketing live stock and a better knowledge of market prices and conditions by farmers in the entire community."

Investigation on raising beef cattle, B. O. Severson (*Pennsylvania Sta. Bul. 138* (1916), pp. 3-20, figs. 8).—This bulletin gives the average results of three years' investigations, the first two of which have been previously reported (E. S. R., 34, p. 171). The objects of the investigation were to determine the possibilities of raising beef cattle in Pennsylvania; whether the demand for "feeders" could be met profitably; the cost of maintaining breeding stock; the cost of raising growing and breeding beef cattle; the cost of finishing beef cattle for market; the value of silage as a sole roughage, and of cotton-seed meal as a supplementary feed; and, finally, to study details of management in the feeding and breeding of beef cattle for profitable production.

Ten Shorthorns composed lot 1 and 10 Aberdeen-Angus lot 2. During the summer months the breeding cows and growing stock were on pasture with no extra feed in the form of grain or roughage. During the winter months corn silage was the sole roughage fed to the breeding and growing stock. Cotton-seed meal was fed, in addition, at the rate of 1 lb. per cow daily, and at the rate of 3 lbs. per 1.000 lbs. live weight, daily, to the growing stock. The fattening stock was fed in accordance with methods proved by experiment to be profitable. The calves ran with their dams and were weaned at from 7 to 11 months of age.

In these three years' experiments the cows were maintained in good condition of flesh, and the weaned calves made satisfactory gains. The normal calves in both lots were vigorous at birth. There was no distinction between the Shorthorn and Aberdeen-Angus breeds in the utilization of feeds, cost of maintenance, or breeding qualities.

The corn silage consumed by each cow during the winter was 9,101 lbs. in lot 1 and 8,920 lbs. in lot 2. Each breeding cow required 1,090 lbs. of straw for bedding, and produced 9,785 lbs. of manure during the winter period. The value of the manure more*than paid for the cost of the labor and bedding required.

The cost of wintering cows during an average winter period of 154.6 days under the conditions of this investigation was more than twice the cost of pas-

turing them for 210.3 days. The total cost of maintaining a beef cow in the Shorthorn lot was \$33.54, and in the Aberdeen-Angus lot, \$34.11.

The breeding results of the experiment indicated that the most important single factor for success in profitable beef production was regularity of the cows in producing calves. Under the conditions of the experiment, 70 per cent calves cost \$49.73 and had a market value of \$50.40, while 80 per cent calves were produced at 6.1 cts. per pound.

The period of gestation was 285 days in both lots. In lot 1 the calves averaged 75.27 lbs. at birth and 671.6 lbs. at twelve months of age, while the heifers at twenty-four months of age averaged 991.6 lbs. In lot 2 the calves averaged 68.36 lbs. at birth and 588.8 lbs. at twelve months, while the heifers at twenty-four months of age averaged 965 lbs. The number of services per pregnancy in lot 1 was 1.63 times and in lot 2, 1.43 times.

Heifers at thirty months of age for breeding purposes cost less than their market value as beef. The steers were of better grade than steers purchased for feeding purposes by the college in the fall of 1913 and costing 7.45 cts. per pound when placed in the feed lot.

The investigation indicates that beef production can be made profitable under present Pennsylvania conditions where the breeding herd is maintained largely on roughage during the winter and on pasture during the summer, when cattle of insured beef type are used, and when more than 70 per cent calves are raised annually.

Shorthorn cattle, A. H. Sanders (Chicago: Sanders Publishing Co., 1916, pp. 840, pls. 61, figs. 3).—This book is a very comprehensive treatise on the origin and development of the Shorthorn breed of cattle, and their introduction, progress, and future in the United States.

Twinning in cattle, with special reference to the free martin, L. J. Cole (Abs. in Science, n. ser., 43 (1916), No. 1101, pp. 177, 178).—A study of 303 multiple births in cattle showed 43 cases as homosexual male, 165 cases recorded as heterosexual (male and female), 88 cases as homosexual female, and 7 cases of triplets, a ratio of twins of approximately 1:4:2, instead of the expected 1:2:1. The expectation is brought more nearly into harmony with the facts by assuming that in addition to ordinary fraternal (dizygotic) twins, there are numbers of "identical" (monozygotic) twins of both sexes, and that while in the case of females these are both normal, in the case of a dividing male zygote to form two individuals in one of them the sexual organs remain in the undifferentiated stage, so that the animal superficially resembles a female and is ordinarily recorded as such, although it is barren. The records for monozygotic twins accordingly go to increase the homosexual female and the heterosexual classes, while the homosexual male class, in which part of them really belong, does not receive any increment.

The theory of the free martin, F. R. LILLIE (Science, n. ser., 43 (1916), No. 1113, pp. 611-613).—A preliminary report of embryological investigations of the subject in which the author takes exception to the theory supported by Cole (see above) that the sterile free martin is really a male cozygotic with its mate.

An anatomical classification of 41 cases of bovine twins, all examined in utero, gave a ratio of 1433:213:3:3:3. It is concluded from the examination of these 41 cases that about 97.5 per cent of bovine twins are monochorial, but in spite of this nearly all are dizygotic. In cattle a twin pregnancy is almost always a result of the fertilization of an ovum from each ovary. The rapid elongating ova meet and fuse and the blood vessels of the two circulations anastomose so that a constant interchange of blood takes place. "If both are males or both are females no harm results from this; but if one is

male and the other female, the reproductive system of the female is largely suppressed, and certain male organs even develop in the female. This is unquestionably to be interpreted as a case of hormone action." The author states that fertile free martins in cattle may be due to a monochorial condition in which the circulation of each fetus is closed.

Caracul sheep, F. R. MARSHALL, L. L. HELLER, and V. O. McWhorter (U. S. Dept. Agr. Yearbook 1915, pp. 249-262, pls. 12).—This article treats of the breed characteristics of caracul sheep, their introduction into the United States and other countries, breeding methods, time and method of removing the skins, and classes of fur.

In experiments in crossing caracul rams and ewes of other breeds, conducted by this Department, poor results were obtained from the use of Cheviot and Merino ewes, thus indicating that none of the fine or medium wool breeds are likely to have much value in the production of fur-bearing lambs. Somewhat better results were obtained with Cotswold ewes. Crosses made with Barbados ewes gave skins of an inferior grade.

Fifteen half-bred caracul-Barbados yearling ewes were bred to an imported caracul ram, with considerable variation in the character of the offspring. Experiments were also conducted in crossing half-bred caracul rams and Barbados ewes. The results were not altogether satisfactory, and it is concluded that there is little prospect of securing marketable skins by breeding half-bred rams to ewes of any class. However, it is stated that a ram having one-half caracul blood will add to a flock an infusion of the body features which this breed shows and will in a small measure and at low cost improve a flock that is to be later bred up for fur production.

Observations show that the value of the skins may be often greatly lessened by allowing the lambs to reach too great an age. Occasionally a skin will improve in luster during the first few days after birth. It was found that in most cases the curl retained its original closeness until the third day, and that in about one-half the skins it had begun to open on the fifth day, while on the ninth day it had opened considerably. The luster improved in most cases up to the fifth day, the change being most marked in skins having a poor luster at birth.

Lamb-breeding tests, H. C. Wilson and A. J. Whelan (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 3, pp. 129-137, ftgs. 7).—This reports a series of experiments conducted at the State Research Farm, Werribee, to determine the most profitable type of lamb to raise for export purposes and local trade.

First cross Lincoln Merino ewes of uniform quality were selected, and these were mated with representative rams of different breeds. The average lambing percentages for three years were Lincoln 92.3, Border Leicester 87.16, Dorset Horn 90.3, Shropshire 84, and Southdown 89.5, with English Leicester 91 as an average for two years.

At seventeen weeks the wether lambs of each of these crosses were weaned and sold in the market. The ewe lambs from each cross were retained for three weeks after the sale of the wethers and shorn, and the fleeces were classed and valued.

The data for the three years are given in detail.

A peculiar breed of goats, J. J. Hooper (Science, n. ser., 43 (1916), No. 1112, p. 571).—An account of a breed of goats raised in central and eastern Tennessee. It is stated that when suddenly frightened the hind legs become stiff and the animal jumps along until it recovers and trots off normally, or if greatly frightened the front legs become stiff also and the goat falls to the ground in a rigid condition. They have received the name of "stiff-legged" or "sensitive" goats,

[Pig-feeding experiments], M. J. CRONIN (Dept. Agr. and Tech. Instr. Ireland, Dept. Com. Irish Pig-Breeding Indus., Minutes of Evidence, etc., 1915, p. 19).—A comparison of cooked and uncooked meals for 42-lb. pigs favored the latter.

Further developments in ovariotomized fowl, H. D. Goodale (Biol. Bul. Mar. Biol. Lab. Woods Hole, 30 (1916), No. 4, pp. 286-293).—The development of several castrated Brown Leghorn females is described.

These individuals developed male plumage and other male characters. After a time, however, certain changes in the plumage of some individuals took place, best described as a change to or toward the female type, as the case might be. Still later the plumage changed again to or toward the male type. An examination showed that no regeneration of the ovary had occurred in these individuals, but that instead an organ sui generis had grown. A portion of the organ was removed from each bird and sectioned, and its structure found to be clearly neither that of the ovary nor that of the testes. The exact nature of these organs has not been determined, but their structure suggested that they have some relation to the epididymis.

The simultaneous administration of pituitary and thymus to growing chicks, S. S. Maxwell (Univ. Cal. Pubs., Physiol., 5 (1916), No. 2, pp. 5-8).—
The results of these experiments show that in the early stages of growth the pituitary feeding exerts a retarding influence which is more marked when a larger amount is administered, and that this retarding effect is not prevented by the simultaneous administration of thymus substance. When the birds were killed and weighings made of the ovary and testes, adrenals, thymus, thyroid, heart, and spleen, no constant difference was found between the pituitary-fed birds and the controls, except in the case of the thymus, which, despite the thymus administered, was much smaller in the pituitary-fed birds than in the controls. It is deemed probable that in these experiments the retardation of growth of the thymus and of increase in body weight are both due to the effect of the pituitary substance.

Experiments with laying hens, W. J. Buss (Ohio. Sta. Bul. 291 (1916), pp. 185-217).—A series of experiments was conducted to compare the egg production of hens kept in close confinement with that of hens allowed practically free range. The following table summarizes the three experiments:

Experi-	Condition,	Dura- tion.	Average number in lot.	Mortal- ity.	Gain or loss in weight per hen.	Cost of feed per hen.	Eggs per hen.	Cost of feed per dozen eggs.	Value of eggs per hen.
1 1 2 2 3 3	Confined On range Confined On range Confined On range	Days. 882 882 728 728 364 364	85 96 51 54 91 03	Per ct. 23, 23 15, 53 17, 50 12, 30 20, 00 21, 80	Pound. -0.16 09 +.02 +.04 +.41 +.47	\$1.96 1.97 1.69 1.74 .74 .79	241 278 244 316 90 129	Cents. 9. 75 8. 49 8. 31 6. 59 9. 95 7. 30	\$4. 22 4. 85 4. 57 6. 01 1. 69 2. 4

Range v. confinement for laying hens.

Experiments were conducted to determine whether rations containing a large variety of feeds give an increase in returns sufficient to justify the extra trouble and expense involved in providing them. Lot 1 received shelled corn and a mash composed of ground corn and meat scrap about 8:5; lot 2, shelled corn and a mash composed of ground corn, bran, and meat scrap; and lot 3, shelled corn, wheat, and oats, and a mash composed in one test of

ground corn, bran, and meat scrap 10:10:7 and in the other of ground corn, bran, middlings, oil meat, and meat scrap 3:4:4:1:2. The results of the two experiments are summarized in the following table:

Variety and simple rations for laying hens.

Experiments.	Duration.	Lot.	Average number in lot.	Mor- tality.	Gain in weight per hen.	Cost of feed per hen.	Eggs per	Cost of feed per dozen eggs.	Value of eggs per hen.
1 1 1 2 2 2	Days. 1,047 1,047 1,047 672 672 672	1	21 19 22 22 22 21 24	Per cent. 29.2 37.5 33.3 20.0 32.0 8.0	Pound. 0.48 .53 .34 .36 .36	\$2. 27 2. 19 2. 77 1. 35 1. 35 1. 84	351 293 371 186 190 202	Cents. 7.74 8.99 8.98 8.73 8.54 10.96	\$6. 45 5. 28 6. 88 3. 44 3. 50 3. 82

In an experiment conducted for 364 days to study the effect of rations containing approximately 10, 15, and 20 per cent of protein upon the rate and economy of egg production by pullets, the grain mixture for all lots was made up of shelled corn and wheat 3:1. The mash mixtures for the different lots were composed of ground corn, bran, and meat scrap in the following proportions: Lot 1, 11:3:1; lot 2, 6:3:6; lot 3, 1:3:11.

The results are summarized in the following table:

Effect of varying the protein content of rations for pullets.

Lot.	Protein content of ration.	Breed.	Average number in lot.	Mortal- ity	Gain or loss in weight per pullet.	Cost of feed per pullet.	Eggs per pullet.	Cost of feed per dozen eggs.	Value of eggs per pullet.
1 2 3 1 2 3	Per cent. 10 15 20 10 15 20 20	B. P. Feeding acorns to fowls, A. Hink (Deut. Tierärztl. Wehnschr., 23 (1915), No. 22. p. 169; abs. in Deut. Landw. Tierzucht, 19 (1915), No. 29, pp. 228, 229).—Acorns were decorticated, pounded, and dried, mixed with bran and sugar, and 30 gm. daily per fowl added to the ordinary feed mixture.

The result was a decrease in egg laying, culminating in complete cessation. The yolk of the eggs was covered with a dirty colored brown membrane, the interior of the yolk also being affected. It is thought that these results are due to the tannin contained in the acorns. The albumin tannate formed in the digestive tract passes in the form of tannate of albumin and tannate of soda into the blood, where fresh tannin is liberated, and exercises its astringent action upon the capillaries of the ovary. The brownish color of the yolk of the egg is due to oxidation.

Poultry management; care of breeding stock and chicks, E. J. Peterson (North Dakota Sta. Circ. 11 (1916), pp. 10, figs. 4).—A general discussion of methods of poultry management.

A study of the preparation of frozen and dried eggs in the producing section, Mary E. Pennington, M. K. Jenkins, W. A. Stocking et al. (U. S. Dept. Agr. Bul. 224 (1916), pp. 99, pls. 17. figs. 7).—Descriptions and laboratory findings as to the various types of eggs occurring in the egg-breaking season have been previously noted (E. S. R., 31, p. 570). Details of the practical application of the principles of construction and equipment of egg-breaking establishments, observations in the packing house, the organization of candling room, breaking room, and wash room in accordance with suggestions made for improvement, and the laboratory findings in samples of the commercial product are correlated, discussed, and summarized in the present bulletin.

It was found in this study, carried on at a number of commercial egg-breaking houses in 1911 and 1912, that eggs commonly used for breaking stock by reputable firms are the small and oversized eggs, dirty and cracked eggs, and shrunken eggs. To check deterioration the eggs should be held in chilled surroundings before and during the process of candling, breaking, and mixing preparatory to freezing or drying.

All eggs, even during the spring months, should be candled previous to breaking. In order to insure well-candled eggs going to the breakage room the system of candling should be such that the work of the individual candlers is checked, and to prevent waste the eggs difficult to grade should be set aside by the regular candlers to be recandled by an expert. All eggs used in the preparation of frozen and dried eggs should be graded out of the shell as well as by the candle, because certain heavily infected eggs, such as sour eggs and eggs with green whites, can only be detected when broken.

In order to insure a good product, bacterial cleanliness and careful grading must be obtained during the process of preparation. The fingers of the breakers should be kept dry and clean. Not more than three eggs should be broken into a cup before emptying, and good eggs should not be saved when a bad egg has been broken into a cup with them. White and yolk are contaminated less by the mechanical than by the shell method of separation, and only clean eggs should be separated by the latter process.

The percentage of "rots" rejected on candling and the organisms in the liquid egg saved increases as the season advances.

Canned eggs with the majority of samples having counts of less than 5,000,000 bacteria per gram, and with 100,000 Bacillus coli or less can be prepared in the producing section from regular breaking stock, provided strict cleanliness and careful grading have been observed. The ammoniacal nitrogen will very seldom be over 0.0024 per cent on the wet basis or 0.0087 per cent on the dry basis. The amount of ammoniacal nitrogen in desiccated egg, however, is not deemed a reliable index to the quality of the raw material from which it is prepared, because this substance is volatilized unevenly during the process of desiccation.

A second-grade frozen product sometimes prepared from eggs showing incipient decomposition to the senses, such as "beginning sours" and eggs with green whites, was found not only heavily infected but chemically decomposed and unfit for food purposes. Only two grades of canned eggs should be prepared when grading eggs out of the shell, viz, food egg and tanners' egg. Leaking eggs handled on special trays between candling and breaking room and graded carefully are as fit for breaking as regular breaking stock. Tanners' egg contains markedly larger numbers of bacteria and larger amounts of ammoniacal nitrogen than does food egg.

The control of the supply of air to drying belts to prevent saturation from the liquid egg is an important factor in preventing multiplication of bacteria in the product during the process of desiccation. The following eggs should be discarded during grading: Black, white, mixed, and sour rots, eggs with green whites, eggs with stuck yolks, musty eggs, moldy eggs, "blood rings," eggs containing diffuse blood, and eggs with abnormal odor. An appendix gives details of the conditions observed in the various establishments studied.

The bacterial infection of fresh eggs, P. B. Hadley and Dorothy W. Caldwell (Rhode Island Sta. Bul. 164 (1916), pp. 3-70, figs. 3).—After a historical résumé of investigations on the bacterial infection of eggs this bulletin takes up a report of experiments begun in 1911. The results of the study are summarized as follows:

Of 2,520 fresh eggs examined by the indirect method 8.7 per cent showed bacterial infection in the yolk. None of the 111 whites examined showed infection, while the yolks of the same eggs gave a percentage slightly less (4.5 per cent) than the average for the series (7.7). The percentage of infection obtained for individual hens per year varied between 2.8 and 15, the average being 9. No hen laid all sterile eggs during any full year. No correlation was observed between percentage of infection and hatchability, or between the percentage of infection and the fecundity, age of the hens, or season of the year. The percentage of infection for infertile and for fertilized eggs was essentially the same. The nature of the infecting organisms occurring in the eggs was briefly studied, and 40 bacterial types were obtained, including 11 cocci, 28 rods, and 1 spirillum.

It is concluded that the most probable source of primary egg infection is the ovaries of the fowl, which become infected by bacteria escaping through the intestinal wall into the portal circulation. The nature of the bacterial species occurring in the primary infection makes clear the fact that primary infection plays no rôle in bringing about the decomposition of eggs. For the factors determining this result we must look mainly to the secondary infections. The nature and extent of the normal primary infection stands in no causal relation to embryo mortality in incubating eggs, and losses in "dead-in-shell" eggs can not be explained on these grounds.

A bibliography of literature cited is given.

DAIRY FARMING-DAIRYING.

The value of raw, steamed, and ensiled raw and steamed potatoes for milk production, W. Völtz and W. Dietrich (Landw. Jahrb., 48 (1915), No. 4, pp. 535-569).—Potatoes prepared in various ways were tested as a supplement to a basal ration of meadow hay, oat straw, and brewers' grains.

Steamed potatoes and ensited raw potatoes had little effect on the milk yield, but material gains were obtained from the feeding of ensited steamed potatoes. The highest milk yield was obtained from raw potatoes and was 2.5 times the yield from steamed potatoes,

With all four preparations the fat and dry-matter contents of the milk were increased, the fat content being especially high with the raw ensiled and the steamed potatoes. The greater quantity of protein and fat-free dry matter were obtained from raw potatoes, followed by ensiled steamed and steamed potatoes.

Mangolds or swede turnips for dairy cows, J. J. Dunne (Jour. Bd. Agr. [London], 23 (1916), No. 1, pp. 58-65).—Comparisons were made at the Danish State Experimental Laboratory of the feeding value of swede turnips and mangolds for dairy cows. The average daily milk yield of the mangold-fed cows was 30.73 lbs. and for the turnip-fed cows, 31.46 lbs., while the fat percentages were 3.06 and 3.01, respectively. Little or no difference in the nutritive

value of roots of different percentages of solids was disclosed by the experiments, when these were used in conformity with their content of solids.

Nutritive value and digestibility of Juneus effusus and Scirpus lacustris used as litter, N. von Ertzporff-Kupffer (Landw. Jahrb., 48 (1915), No. 3, pp. 429-487).—In digestion experiments with rabbits it was found that J. effusus when freed from fat was readily eaten by the animals but was not well digested.

Feeding experiments with milch cows showed that a daily ration of 13 lbs. of *S. lacustris* hay had no bad effect upon their health but that the milk yield was decreased even if as low as 4.5 lbs. per head were fed. The percentages of the fat and total solids of the milk were not altered but the absolute quantity of these constituents was decreased. Feeding *S. lacustris* hay did not change the consistency, flavor, taste, or color of the butter but the Reichert-Meissl number was decreased and the iodin value increased.

The author considers these two plants to be of considerable value as litter.

Cooling milk, H. E. Ross and T. J. McINERNEY (Cornell Reading Courses, 5 (1915), No. 102. pp. 55-71. figs. 6).—This pamphlet treats of methods of cooling milk and types of coolers.

The results of experiments indicate that the bacteria content of milk held at a temperature of 50° F, increases slowly, while that of milk held at 90° increases rapidly whether the milk had either a small or a large number of bacteria in it originally.

Cooling milk by placing the cans in a tank of ice water is deemed a practical method for use on farm dairies. To cool the milk rapidly it must be stirred at frequent intervals, but stirring every 5 minutes caused a sufficiently rapid drop in temperature and the difference from stirring at intervals of 10 minutes was very slight. When sufficient quantities of ice were used stirring the water in the cooling tank had little effect on the rapidity of cooling.

In order to obtain the highest efficiency from the conical type of cooler it is absolutely necessary to stir the water inside the cooler. Lower temperatures can be obtained by using brine and ice than with ice water alone.

Artificial refrigeration (Milk Dealer, 5 (1916), No. 8, pp. 26, 30).—From milk plant surveys made by the Dairy Division of the U. S. Department of Agriculture, data were obtained on the cost of ice in plants where no refrigerating machines were used, and on the cost of operating the machines in plants where they were used. These figures were obtained from some of the smaller-sized plants in the east North Central States, and in all cases electric power was used for operating the compressor, so that very reliable costs could be obtained on this item. The power also included, in many cases, the amount used in operating the pasteurizer, bottle washer, etc. Some of the plants bought a small amount of ice for the delivery wagons. The overhead expense on the machine was figured at 16 per cent on the cost, 6 per cent interest on the money invested, and 10 per cent depreciation.

The average cost per year per gallon of daily capacity of plant in thirteen plants using artificial refrigeration was \$1.44. The average cost in nine plants using ice was \$2.25. It is pointed out, however, that these figures do not necessarily indicate that it is more economical for all plants to use artificial refrigeration, as the size of the plant and individual conditions must be determined by each dealer for himself.

A new method for the destruction of bacteria in large volumes of milk by means of electricity, F. C. Lewis (Jour. Bd. Agr. [London], 22 (1916), No. 12, pp. 1229-1238, pls. 2, fig. 1).—A method of destroying bacteria in milk by means of electricity is described. The essential feature of the method consists in passing a suitable current of electricity through the milk during its passage

through a tube connecting a container with a receiving vessel. The electric current so acts that the major portion of all bacteria in the milk is killed, and no chemical alteration in the milk so treated has been observed.

Judged from the standpoint of the percentage reduction, the electrical method gave highly satisfactory results (over 99.9 per cent) as well as from the standpoint of the presence of *Bacillus coli* (or manurial contamination).

The results of feeding tubercle-bacilli-containing milk, treated and untreated, to guinea pigs also indicated that the electrical treatment is an effective destroyer of the tubercle bacilli.

It is stated that even in the hottest weather the milk is perfectly fresh for three or four days after treatment. The change which ultimately takes place is a characteristic one, viz, a mild, pleasant, acid reaction and flavor. The putrefaction which is noticeable so often in stale steam "sterilized" milk has never been observed. Milk treated by this electrical process is deemed perfectly suitable as a medium for the action of culture ferments.

The electrical treatment of milk for infant feeding, J. M. Beatte (Jour. State Med., 24 (1916), No. 4, pp. 97-113, figs. 4).—Experimental data are given which indicate that a rapidly alternating current of electricity is efficient in reducing the bacterial content of milk to a minimum without impairing the chemical constitution of the milk. Bacteriological tests of treated and untreated milk, supplemented by animal inoculation experiments, showed that disease-producing bacteria, including Bacillus tuberculosis, were destroyed by the method. "The milk is not sterilized in the strictest sense of the word, but there is a reduction in the total number of bacteria by 99.93 per cent, and . . . the milk will keep perfectly sweet for at least three or four days after treatment. . . The taste is not in any way altered." In the author's opinion, this milk is perfectly satisfactory as a food for infants.

Scoring of milk and cream, W. M. ESTEN and CHRISTIE J. MASON (Connecticut Storrs Sta. Bul. 83 (1915), p. 135).—Standards used in the scoring of milk and cream for acidity and bacterial count in a dairyman's contest are given, and the results briefly reported.

The production of first-grade cream in Oklahoma, R. C. Potts (Oklahoma Sta. Bul. 108 (1916), pp. 3-11, figs. 5).—The topics discussed in this bulletin are the requirements for producing first-grade cream, the necessity of low temperature, acidity of mixed cream, agencies for keeping cream cold, cooling cream with well water, and insulated refrigerator cream tanks. Charts and a table show the relation of temperature and age of cream to the development of acidity in each separate skimming.

Tests and comparisons of commercial lactic starters, Christie J. Mason (Connecticut Storrs Sta. Bul. 83 (1915), pp. 112–125).—This reports tests and comparisons made of six commercial starters, the strongest and most uniform of which is reported as Ericsson's milk culture.

It is stated that transferring milk cultures of *B. lactis acidi* daily will in most cases increase the activity of the bacteria. Those not sufficiently active after the fourth or fifth transfer are of doubtful value. Cultures intended for use as starters should be propagated at as low a temperature as is used for ripening the milk or cream. Results of the experiments made indicate that the kinds of media best adapted for the long keeping of this class of lactic organisms are milk with calcium carbonate added and standard bouillon containing 1 per cent of saccharose. Sealing tubes with paraffin assists in maintaining the activity of cultures kept for long periods of time.

Ice cream. Evaporated milk (Maine Sta. Off. Insp. 76 (1916), pp. 9-20).—Analyses are given of various brands of evaporated and condensed milk and notes on the examination of ice cream.

Bacterial studies of Camembert cheese, W. M. ESTEN and CHRISTIE J. MASON (Connecticut Storrs Sta. Bul. 83 (1915), pp. 103-111).—In bacterial examinations of Camembert cheese from many different sources it was found that the highest numbers of bacteria were usually found about the third day, after which the numbers decreased, and most rapidly between the seventh and eleventh days. With fluctuations the numbers decreased gradually until the cheeses were ripe. In the majority of cases 99 per cent or more of the bacteria in the interior of the cheese were of the lactic acid type. The proportion of liquefying types was small, especially where a starter was used, as was generally done.

In a comparison of the types of *Bacterium lactis acidi* found in European and American cheeses, the European form made somewhat larger colonies in litmus lactose gelatin plates and grew on the surface, while the American form was always found below the surface. The European form grew more abundantly on agar slants and in bouillon. Milk soured with cultures of the two forms developed no noticeable difference in flavor or odor either when first curdled or when kept for four weeks at the temperature used for ripening cheese. Cheeses made with starters of these two types showed no real difference in flavor.

Practically every cheese tested showed the presence of yeasts. They were most abundant on the surface, but were uniformly found in the curd. Rarely the numbers reached several millions per gram, but in most cases there were only a few thousands per gram, the highest numbers being usually found between the fourteenth and twenty-first days. Several different species were found, the most common being an acid producer which in litmus lactose gelatin resembled *B. lactis arogenes*. Several cases of gassy cheese were apparently due to yeasts. Some of the yeasts from cheese produced in milk an acid, others an alkaline reaction; some peptonized milk. Those tested were able to develop in the absence of air, but not so rapidly as in aerobic conditions. They were not greatly restrained by amounts of salt as large as are present in cheese.

The acidity of 10 samples ranged from 1.67 to 3.2 per cent. The presence of *Bacillus bulgaricus* was ascertained, but it is stated that it is doubtful if this organism has any decided influence on the ripening of Camembert, since it grows best at from 44 to 45° C. and only very slowly at the lower temperatures, from 10 to 15°, at which Camembert ripens. As Camembert ripens within five weeks it is also very doubtful if *B. bulgaricus* could develop sufficiently in that time to affect the flavor.

Tests showed only one-ninth as many bacteria under anaerobic as under aerobic conditions, and in tests of the slime only one-fortieth as many. No species were found in anaerobic cultures which were not present in the aerobic.

Bacterial counts were made from the slime of cheeses of different origin. The surface slime contained a great number of different types of organisms. However, it is thought that they contribute but little to the production of flavor.

Tests conducted with Roquefort cheese gave results very similar to those given for Camembert. The lactic acid bacillus, *B. lactis acidi*, was always found in nearly pure cultures and other species did not appear uniformly enough to suggest any special importance in ripening the cheese. Yeasts were present in four out of the five important brands examined. *B. bulgaricus* is probably almost always present in Roquefort cheese. Tests of acidity showed a range of from 1.64 to 4.95 per cent. *B. bulgaricus* was also found in other

soft cheeses, as Neufchatel and Gorgonzola. Anaerobic cultures developed no species not found in the aerobic cultures.

Classification and nomenclature of lactic-acid organisms, F. LÖHNIS (Milchw. Zentbl., 45 (1916), No. 4, pp. 49-51; abs. in Cream. and Milk Plant Mo., 4 (1916), No. 8, pp. 18, 19).—This is a paper presented by F. Löhnis at the sixth International Dairy Congress, in which he defends his classification of lactic-acid organisms, as published in his Handbook of Agricultural Bacteriology in 1910 (E. S. R., 23, p. 720).

It is stated that "the establishment of these groups has been criticized adversely. Although it was recognized that the organisms of group 2 were closely related to the typical streptococci it was insisted that they be placed among the bacteria, owing to their generally elongated form. In that case it would have been necessary to place the related streptococci also among the bacteria. Aside from the uniform character of the streptococci from a physiological viewpoint there would be grave practical objections to further enlarging a genus that already embraces many organisms of widely different natures.

"It was proposed to separate the micrococci from the lactic-acid bacteria on account of their ability to dissolve casein. This would leave in group 4 only such micrococci as possessed no proteolytic properties. But this property is known to be highly inconsistent, and its adoption as a criterion of classification would greatly impair the natural grouping.

"These criticisms and others, including those of Rogers and Gorini, are attributed by the author to failure to distinguish accurately at all times whether the classification is intended for practical or for scientific purposes, which may agree but may also diverge. From a practical viewpoint it is quite justified to comprehend liquefying micrococci and other casein-dissolving bacteria under such a name as casease bacteria. Likewise the nature and intensity of lactic-acid production may be of practical importance, leading to a distinction between true and false lactic-acid bacteria. But, for scientific classification, the international rules of botanical momenclature must be accepted. In the establishment of groups it is necessary to include related forms although they may not generate acid. It is no more possible to find a system based on scientific grounds for the lactic-acid bacteria alone, to say nothing of the so-called true lactic-acid bacteria, than it would be to find one for flowering plants that produce fragrance. Practical purposes can be fully met by making suitable subdivisions of types within the groups, as between acid-forming, casein-dissolving, and slime-producing varieties."

VETERINARY MEDICINE.

Animal disease and our food supply, E. B. MITCHELL (U. S. Dept. Agr. Yearbook 1915, pp. 159-172, pls. 2).—This article, prepared under the direction of the chief of the Bureau of Animal Industry, is a popular discussion of the relation of animal disease to food supply. Attention is called to the fact that while during the recent outbreak of foot-and-mouth disease 168,158 animals valued at approximately \$5,676,000 were destroyed this represented less than 0.1 per cent of the total number of cattle, sheep, and swine on the farms of the country. The money that the country paid to rid itself of an exceptionally costly outbreak was less than 3 per cent of the annual tax that other animal diseases levy upon it.

Economic importance of the Federal inspection of meats, G. Ditewig (U. S. Dept. Agr. Yearbook 1915, pp. 273-280).—A popular discussion.

Investigations on the disinfectant strength of disinfectants in relation to their concentration, J. P. Gregersen (Centbl. Bakt. [etc.], 1. Abt., Orig., 77 (1915), No. 2, pp. 168-185).—Experimental data submitted indicate that the reciprocal of the time in which an antiseptic kills a given micro-organism may serve as a measure of the disinfectant strength of the material under given conditions of concentration and temperature. The disinfectant strength of aqueous solutions of hydrochloric acid, mercuric chlorid, iodin-potassium iodid, and formaldehyde is proportional to the concentration. For aqueous solutions of phenol, thymol, and chloral hydrate the disinfectant strength is proportional to the fourth power of the concentration of the material.

The product of the concentration and the time is designated as the "disinfectant constant." To compare the disinfectant strengths of various materials the relation between the reciprocal values of their disinfectant constants can be used.

The formation of specific proteoclastic ferments in response to the parenteral injection of foreign proteins, Florence Hulton (Jour. Biol. Chem., 25 (1916), No. 1, pp. 163–171).—" Protamin, phaseolin, and gliadin are not digested to any degree by either normal serum or that of an animal injected with these substances. Casein and soy-bean globulin are digested to a greater extent by the normal serum than by that of the injected animal. Edestin and milk albumin are digested to the same degree by the normal and experimental serum. Bence-Jones protein is digested to a marked degree by both sera and equally well in each case."

Earlier work on the subject is briefly reviewed and a bibliography of the important contributions included. See also a previous note by Taylor and Hulton (E. S. R., 34, p. 578).

Cachexia following the parenteral injection of homogenous organ proteins, H. Dold (Ztschr. Immunitätsf. u. Expt. Ther., 1, Orig., 24 (1916), No. 4, pp. 355-360).—Confirming the findings of earlier investigators it is shown that the repeated parenteral injection of sterile aqueous organ extracts into rabbits and guinea pigs causes a decided emaciation. In rabbits the loss varied from 12 to 18 per cent in from 11 to 14 days. In guinea pigs the loss varied from 18 to 24 per cent in 31 days.

Histologically the organs of the animals indicated a general atrophy. An acute inflammation was manifest at the site of injection.

On the mechanism of the cleavage process in Abderhalden's dialysis procedure, F. Plaut (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1916), No. 4, pp. 361-379).—It is indicated that in the dialysis procedure the organ substrate has a nonspecific hemolytic action. By digesting the substrate with serum this action can be preserved. By the repeated digestion with blood these organ preparations become antihemolytic. These phenomena are attributable to the adsorption of protein and are similar to the behavior of inorganic suspension colloids.

The significance of these phenomena in connection with the dialysis procedure is indicated. The adsorption capacity can be greatly reduced and the disturbing side reactions weakened by thoroughly boiling the organ substrate shortly before using, as well as by the complete removal of blood.

The Abderhalden dialysis procedure used in testing the serum of horses, Bernhardt and Hofher (Berlin. Tierärztl. Wehnsehr., 31 (1915), No. 33, pp. 385-389).—The investigation has demonstrated that the serum of horses contains protein-cleaving enzyms, and that these enzyms can be detected in the serum even after a fasting period of 26 hours. They are easily inactivated by heating at from 56 to 60° C. The age and hemolytic properties of the serum have a marked influence on the intensity of the ninhydrin reaction, so that

hemolytic serum and that which is more than 24 hours old should not be used in the dialysis procedure. From the experimental results, it is concluded that on account of the presence of the digestive ferments in the serum of the horse the dialysis procedure for the detection of pregnancy is only of value when it can be definitely established that the serum is nearly free from these ferments.

Investigations on the control of foot-and-mouth disease with "rindol," MATTHIESEN and GLÄSSER (Berlin. Tierürztl. Wehnschr., 32 (1916), No. 10, pp. 109-114).—The authors have demonstrated that the preparation "rindol," administered as directed by the producer, has no curative effect on diseased animals, nor does it confer any immunity on healthy animals which may subsequently be exposed to infection. The experimental data, together with the clinical findings, are reported in detail.

Contributions to the serodiagnosis of glanders; the use of polyvalent extracts in the examination of the serum for complement deviation, W. Pfeiler (Berlin. Tierärztl. Wehnschr., 31 (1915), Nos. 34, pp. 397-403; 35, pp. 411-413).—Experimental data obtained in the course of an investigation on the improvement of the serodiagnostic methods for the detection of glanders are submitted. It was found that the use of polyvalent extracts in the complement-deviation procedure increased the sensitiveness of the reaction considerably. The experimental results are discussed in detail.

The agglutinin, precipitin, and complement-deviating substance content of the aqueous and vitreous humor and other body fluids of glanderous horses, Borchard (Arch. Wiss. u. Prakt. Tierheilk., 41 (1915), No. 6, pp. 373-425).—It has been observed that the synovial fluid and the serous fluids of the pericardial, peritoneal, and pleural cavities contain appreciable amounts of agglutinin, precipitin, and complement-deviating substances. The aqueous and vitreous humor, however, contains none, or only extremely small amounts, of these antibodies.

A bibliography of 63 references cited is appended.

The toxicity of the blood serum of luetics for anaphylactic (sensitized) guinea pigs, W. Misch (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1916), No. 4, pp. 380-386).—Human syphilitic serum is found to be more toxic for sensitized guinea pigs than the serum of nonsyphilitics. This phenomenon is not manifested when normal untreated guinea pigs are injected with the respective sera. It is indicated that this increased toxicity of luetic serum is caused by an increase of proteins in the serum, especially globulins.

Observations upon complement fixation in the diagnosis of pulmonary tuberculosis, C. F. CRAIG (Amer. Jour. Med. Sci., 150 (1915), No. 6, pp. 781-791; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 10 (1916), No. 2, p. 46).— Experimental data presented demonstrate that "complement-binding antibodies are present in the blood serum of both active and clinically inactive tuberculous infections. A polyvalent antigen prepared from several strains of the human tubercle bacillus has been found to give excellent results in complement fixation for tuberculosis. With the test described complement fixation gave a positive reaction in 96.2 per cent of cases of active tuberculosis and in 66.1 per cent of the cases of clinically inactive tuberculosis. The test was negative in normal individuals and in patients suffering from other diseases with the exception of two patients infected with syphilis in whom symptoms of a coincident tuberculous infection was also present. The test does not give positive results with the blood serum of syphilities in whom there is no coincident tuberculous infection. The reaction, when positive, is specific and apparently indicates the presence of an active tuberculous focus, although there may be no symptoms of the disease present. Positive results are obtained in a large percentage (66 per cent) of clinically inactive cases of pulmonary tuberculosis, and such a result indicates that though it may be quiescent the infection has not disappeared. The results obtained with the test described are practically as good as those obtained with the Wassermann test for syphilis."

The significance of bovine tuberculosis to human tuberculosis, J. ORTH (Naturvissenschaften, 4 (1916), No. 10, pp. 121-124).—This article discusses the relation of two forms of the disease and indicates the necessity of controlling, and exterminating if possible, the bovine form. Some statistical data on the progress of the disease in Germany in children under 15 years of age are included.

Tuberculosis in the dog and its relation to human tuberculosis, H. Markus and H. Schornagel (Folia Microbiol. [Delft], 4 (1916), No. 2, pp. 189–205, pls. 4).—From their observation and experience the authors conclude that the occurrence of canine tuberculosis is more frequent than is ordinarily suspected. The dog is undoubtedly infected in the greatest number of cases by the human organism. Healthy dogs may also become a source of infection for man by carrying the virulent virus from the street (dried sputum, etc.) and thus spreading it in the house. A rational prophylactic measure against the disease in such form is to keep the dog in a sanitary condition.

Tuberculosis in Finmarken (the most northerly part of Norway) with special reference to the living conditions, A. B. Wessel (Tidsskr. Norske Lægefor., 34 (1914), Nos. 5, pp. 222–230, figs. 2; 6, pp. 273–281; 7, pp. 310–326, figs. 14; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 10 (1916), No. 1, p. 14).—The mortality from tuberculosis in this Arctic region is 4.5 per 1.000 and has increased steadily since 1860. The cause of such increase is attributed to a deep-seated house infection. The author gives an interesting detailed description of the living conditions of the various inhabitants of this region, viz, Norwegians, Laps, and Finns.

Studies on the biochemistry and chemotherapy of tuberculosis.—XIV, The tuberculocidal action of arsenic compounds and their distribution in the tuberculous organism, A. Arkin and H. J. Corper (Jour. Infect. Diseases, 18 (1916), No. 4, pp. 335–348. fig. 1).—Continuing previous work (E. S. R., 33. p. 877), experimental data have demonstrated that "sodium arsenite in dilution of from 0.1 to 0.0001 per cent and sodium cacodylate in dilution of from 2 to 0.002 per cent have no germicidal action on human tubercle bacilli in 24 hours at 37° C. Mercury cacodylate in dilutions of from 1 to 0.001 per cent has a germicidal action on human tubercle bacilli in 24 hours at 37°. This action is in all probability due to the mercury and not to the cacodylate radical. Atoxyl, arsacetin, and neosalvarsan in dilutions of from 1 to 0.001 per cent have no germicidal action on human tubercle bacilli in 24 hours at 37°."

It is evident that these inorganic and organic preparations of arsenic have no specific action on human tubercle bacilli, and if of any therapeutic value at all it is because of their favorable influence on metabolism in general. The arsenic was found in the liver, lungs, kidneys, blood, spleen, and tubercular tissues (lymph glands of the guinea pig and eye of the rabbit), the concentrations in these different tissues not varying to a great extent. There was no evidence of accumulation in the tuberculous tissues.

Sodium stannate in a concentration of 1 per cent was not germicidal toward tubercle bacilli in 48 hours at 37°.

Studies on the biochemistry and chemotherapy of tuberculosis.—XV, The bactericidal and fungicidal action of copper salts, Lydia M. DeWitt and Hope Sherman (Jour. Infect. Diseases, 18 (1916), No. 4, pp. 368-382).—It is concluded that copper, either as a bactericide or as a fungicide, is unsatisfactory and unreliable, especially when used for only short periods of time.

A certain selective specificity was apparent, in that some organisms were markedly susceptible, while others were very resistant to the action of copper.

Copper is but slightly bactericidal for the tubercle bacillus, although dilutions of 1:100,000 prevent its growth in the test tube. In general, however, it was not possible to show any specific affinity of copper for tuberculous tissues.

Contributions to the serodiagnosis of typhus, Papamarku (Centbl. Bakt. [ctc.], 1. Abt., Orig., 77 (1915), No. 2, pp. 186–197, figs. 2).—The complement-fixation reaction in typhus, using alcoholic organ extracts as antigen, yields a high percentage of positive results when fresh serum from sick and convalescent patients is used. The percentage of positive results is greatly reduced by using inactive sera. The reaction can be obtained in the third day of the disease, and continuing for a period of two weeks. It is probably specific, although positive reactions have been obtained by the use of syphilitic as well as typhus-fever organ extracts as antigen.

"Lungworms," a preliminary report on treatment, with some observations regarding the epidemiology and life history of the parasite, W. B. Herms and S. B. Freeborn (California Sta. Circ. 148 (1916), pp. 8, figs. 2).—The data here presented relate to three species of lungworms of economic importance in California, namely, Dictyocaulus viviparous affecting calves, deer, and rarely sheep; D. filaria affecting sheep, goats, camels, deer, and sometimes calves; and Metastrongylus apri affecting swine.

In experimental work carried on by E. M. Ledyard with various chemicals, including turpentine, benzin, chloroform, and other substances, used separately and in various combinations, chloroform administered in both nostrils proved to be most effective. A herd of 150 Angora goats was successfully treated with 1.5 cc. of chloroform in each nostril during the fall of 1914. In every instance the animal became slightly anesthetized for a period varying from 2 to 20 minutes, but no bad results developed in the herd, which after two more treatments became apparently free from lungworms. It was supposed at first that chloroform actually killed the lungworms in situ and that they were eliminated by coughing, but it was later found that the chloroform merely stupefied the worms and at the same time irritated the throat and windpipe, thus causing a prolonged paroxysm of coughing during which the worms are coughed up and swallowed.

In searching for a standard safe and effective dose of chloroform, it was found that one animal may require five times the amount needed to produce the same effect in another. This variability has led to the practice of administering enough chloroform to make the treated animal slightly groggy, the maximum dosage having been 11 cc. for calves and 3 cc. for goats. Animals to be treated should be confined in a corral which is free from grass and other vegetation. Half the dose is administered in each nostril, and the action of the chloroform is enhanced by stopping the nostrils with the hand or cotton plugs for a few moments after injection. Two hours after treatment a saline purge of Epsom or Glauber's salts should be given the animals.

Brief reference is made to the life history of these lung parasites. Attention is called to the fact that von Linden and Zenneck report, in an article previously noted (E. S. R., 34, p. 879), observations on two types of embryos, one occurring in the mucus of the trachea and of the space behind the nose, and consisting of slim, strong moving embryos, capable of living outside the body, the other occurring in the lungs and consisting of short, thick, slow moving embryos which are unable to live outside the body. It is pointed out that deer and possibly cows may act as carriers and should be excluded from the pasture land of susceptible stock.

Some lice and mites of the hen, G. H. LAMSON, JR., and J. A. MANTER (Connecticut Storrs Sta. Bul. 86 (1916), pp. 169-196, figs. 15).—A general account is given of the more important lice and mites which commonly attack the domestic fowl, their life history, and remedial measures, together with brief reference to some experimental work with remedies.

The pests thus considered are the large body louse (*Monopon biscriatum*), the small body louse (*M. pallidum*), the head louse (*Lipeurus heterographus*), poultry mite or roost mite (*Dermanyssus gallinæ*), and scabies or scaly leg mite (*Cnemidocoptes mutans*).

The large body louse is one of the species most commonly found upon poultry. Its eggs, which are attached securely to the feathers near the body of the host, were found on chickens to hatch in from five to seven days, the young reaching maturity and laying eggs in somewhat less than 17 days, which would indicate a life cycle of about three weeks. On infested chickens it is more abundant under the wings, but the area most commonly infested on older birds is around the vent, although specimens will be found on the head and scattered about the body. As many as 3,600 individuals were counted from one chicken, and this is thought to have included not more than one-half of those present. The species readily travels from one bird to another and often to other barnyard fowls, having been found by the authors upon turkeys.

The small body louse is reported by most authors to be the commonest louse infesting the hen in the United States. Its general habits and life history are similar to those of the large body louse, but it is usually more abundant around the vent. It has been reported to infest horses which have been stabled near poultry.

The head louse is most prominent on the feathers of the head but is often found on the neck and occasionally on the feathers of the wings. It is much less active than the body lice above mentioned. Its eggs, which are glued to the feathers of the head and neck, hatch on chickens in from four to five days and reach maturity and oviposit in 10 days, the life cycle thus occupying a period of about 15 days. Several less important lice mentioned are *L. variabilis*, usually found upon the feathers of the wing, *Goniocotes abdominalis*, and *G. hologaster* upon the feathers on the underside of the hen.

The most effective control measure tested by the authors for body lice consists in the application of a dilution of mercurial ointment or blue ointment. One hundred and four chickens were treated in a laboratory with this ointment at various strengths, the applications being made to different regions of the body. The normal strength of blue ointment was found to be very effective and even a dilution of this proved satisfactory, but the effectiveness decreased with a decrease in the amount of mercury present. On chickens the most vulnerable point of attack proved to be on the body under the wings, while an application around the vent was also effective. The method recommended consists in parting the feathers and applying an amount of ointment about the size of a pea to the flesh just below the vent. It is pointed out that the use of sulphur and lard, one of the commonest mixtures prescribed for lice on the heads of chickens, is dangerous.

The poultry mite attacks the fowl only at night, when it crawls upon the roost from its hiding place between the boards supporting the roosts and sides of the poultry house. The eggs are laid from early spring until late fall, usually about four eggs being laid in a period of two or three days and repeated at intervals, and hatch in from two to six days. The period required for completing their life cycle depends upon the time required in gaining access to the fowl.

The authors have found carbolineum far more effective than kerosene oil, zenoleum, or carbolic acid in ridding the hen house of these mites, and it is recommended for use where a comparatively small quantity is required, but where large quantities are needed one of the coal-tar mixtures bought by the barrel at a lower rate is preferable. A diagram is given of a roost constructed in a manner to reduce the breeding places of the mites.

The scaly leg mite burrows under the skin and causes large irregular scales and gray masses on the feet of hens. This mite may be killed by any oil preparation which has a penetrating power when applied after the scales have been loosened by soaking and scrubbing the legs with a brush in warm soapy water. The authors have found nothing better than caraway oil mixed with lard 1:4.

The importance of sanitation in the poultry house and on the range is emphasized, and the care of sitting hens, dusting and the use of dust baths, and the use of sulphur on chickens are briefly discussed.

Bacillary white diarrhea of young chicks: Its eradication by the elimination of infected breeding stock, L. F. Rettger, W. F. Kirkpatrick, and R. E. Jones (Connecticut Storrs Sta. Bul. 85 (1915), pp. 151-167, figs. 2).—In this fifth report on studies of white diarrhea of young chicks (E. S. R., 31, p. 484) the authors report upon the eradication of the disease through eliminating the reacting fowls from the breeding stock by means of the agglutination test.

A summary of the work and the conclusions drawn therefrom are as follows: "During the first year of the present campaign against bacillary white diarrhea in this State 14,617 individual fowls and 107 flocks were tested by the macroscopic agglutination test. The number of reacting (infected) fowls was 1,440, or 9.85 per cent of the total number. Of 13,831 hens 1,417, or 10.24 per cent, were positive, and of the 786 males tested 23, or 2.9 per cent, reacted. The testes of two of the males harbored *Bacterium pullorum* in large numbers. In four of the reacting males pericarditis and infection of the heart sac with the same organism was observed.

"The retesting of flocks which on the first examination by this method contained bacillus carriers, and from which the reactors had been removed, gave widely different results. In four flocks out of a total of 13 no reactors were found at the time of the second test. In the other nine the percentage of infection varied from 0.6 to 25.7 per cent, the number in each instance being decidedly less than in the first test. The breeding records obtained from the owners were most encouraging, and with a few exceptions showed a high degree of success as compared with previous years.

"The greatest value of the agglutination test is in its determination of Infected and uninfected flocks. On the basis of 100 per cent of negative tests in a flock the most successful campaign may be waged against bacillary white diarrhea. Only such flocks should be employed as future breeders, and all encouragement should be given to the owners to find a ready market for eggs for hatching and for day-old chicks. On the other hand, where there is no certainty that ovarian infection does not exist the fowls should not be used as breeders until they are known to be free from all taint of the disease,"

RURAL ENGINEERING.

How engineering may help farm life, E. B. McCormick (U. S. Dept. Agr. Yearbook 1915, pp. 101-112, fig. 1).—In a brief discussion of the application of engineering efficiency to farm life and operations, it is pointed out that the engineer can be of special assistance to the farmer in the "economical and

comprehensive use of machinery of various types; the arrangement and grouping of farm buildings and structures, as well as the construction of individual buildings; and the development of natural resources for furnishing power, as a substitute for manual and animal labor now employed at considerable inconvenience and excessive overhead cost."

The law of irrigation, compiled by C. F. Davis (Fort Collins, Colo.: [Compiler], 1915, pp. 346).—This text, comprising 26 lectures, is intended for the secondary schools in the West in which a course in the law of irrigation is given. The lectures aim to give a working knowledge of the law which controls the large number of questions that have arisen from the appropriation and use of water in the western United States and also deal with the history of irrigation and irrigation enterprises in other lands. While the lectures are based primarily upon the law in Colorado, they also point out wherein this law differs from the laws in other States.

Irrigation practice and engineering.—III, Irrigation structures and distribution system, B. A. ETCHEVERRY (New York and London: McGraw-Hill Book Co., 1916, vol. 3, pp. XV+438, pls. 35, figs. 186).—This, the third volume of this work (E. S. R., 34, p. 482), is devoted to that part of irrigation engineering related to irrigation structures and distribution systems. It deals with the following subjects:

Diversion works; diversion weirs; design of diversion weirs; design of diversion weirs of the loose rock-fill Indian type; dynamic forces produced by flow of water over weirs and their effect on the design of weirs; description of diversion weirs; scouring sluices, fish ladders, logways; main head gates or regulator for canal system; gate-lifting devices; canal spillways, escapes, and wasteways; sand gates—sand boxes; crossings with drainage channels; drops and chutes in canals; distribution system; check gates; lateral head gates and delivery gates; road and railroad crossings with canals, culverts, inverted siphons, and bridges; special types of distribution systems—wooden flume, wooden pipe, and cement pipe distribution systems; and measuring devices.

The flow of water in irrigation channels, G. H. Ellis (*Proc. Amer. Soc. Civ. Engin.*, 42 (1916), No. 2, pp. 187-204, pls. 2, flgs. 4).—This paper presents a study of experimental data previously reported by Scobey (E. S. R., 33, p. 183), the result of which was to deduce an experimental formula V=C $R^{0.50}$ $S^{0.5}$ for the flow of water in channels in which the coefficient C varies from about 40 to 140, depending on the roughness of the channel. "For general conditions the following formulas are submitted: For concrete channels, V=105 $R^{0.69}$ $S^{0.5}$; for wooden channels, V=100 $R^{0.69}$ $S^{0.5}$; for earth canals, V=60 $R^{0.69}$ $S^{0.5}$." Incidentally the need of care in the selection of a value for the coefficient of roughness is brought out.

The automatic volumeter, E. G. Hopson (*Proc. Amer. Soc. Civ. Engin.*, 41 (1915), No. 8, pp. 1891–1908, figs. 9).—"This paper describes an apparatus intended to gage the flow of fluids by the collection of a proportionate part of the flow, or its equivalent, in a small vessel where it can be readily measured at any time. This result is accomplished by the use of very small orifices for the purpose of regulating the discharge into or out of the collecting vessel, and other special arrangements whereby the pressure head under which the discharge into the collecting vessel takes place is at all times the equivalent, or a constant ratio, of the velocity head of the liquid or gas being measured. . . .

"The practical operation of the device should probably be first for irrigation uses, and particularly for measurements of individual service flows or flows in small laterals. . . .

"The device, as applied to irrigation use, has the advantage that it is independent of such matters as drifting sand, weeds, or any floating or suspended

trash. Nothing in suspension will pass into the influent pipe, which has practically no velocity of flow and has, moreover, an upward course. Solid matter, if placed in the influent pipe, would, in fact, settle back into the stream. Even if suspended or floating material should get into the measuring vessels, it would not pass through the controlling orifice on account of the internal arrangements."

Diagram giving excess loss of head in 90° bends, F. S. Bailey (*Engin. News*, 75 (1916), No. 9, pp. 412, 413, fig. 1).—This diagram gives the excess loss of head in 90° bends in cast-iron water pipe and is based on a formula proposed by Fuller (E. S. R., 31, p. 384).

Machine for placing concrete lining in canals, E. I. Davis (Engin. News, 75 (1916), No. 6, pp. 264-267, figs. 4).—This is a description of the construction and operation of a machine developed on the U. S. Reclamation Service canal at Hermiston, Oreg. This consists essentially of a traveling form into which concrete, mixed immediately alongside, is dumped and forced out at the bottom to form the lining of the irrigation canal.

Experiments on the economical use of irrigation water in Idaho, D. H. BARK (U. S. Dept. Agr. Bul. 339 (1916), pp. 57, pls. 3, figs. 13).—This report covers the same ground as two previous reports (E. S. R., 29, p. 180; 33, p. 583).

Ground water in San Joaquin Valley, California, W. C. MENDENHALL, R. B. Dole, and H. Stabler (U. S. Geol. Survey, Water-Supply Paper 398 (1916), pp. 310. pls. 5, figs. 4).—This report deals with the occurrence, quality, and utilization of the ground water of an area of about 7,500,000 acres in the Great Central Valley of California, with particular reference to its use for irrigation and domestic purposes. The results of pumping tests on about 50 irrigation plants in the valley are also reported, together with a summary of points to be observed in order to obtain good service from a pumping plant.

With reference to the quanty of the waters of the valley, it is concluded that "the waters of the perennial streams are entirely suitable for irrigation. Storage to remove suspended matter renders them acceptable for boiler use, and filtration would purify them for domestic supply. On the east side between the Sierra and the trough of the valley, wells from 20 to 1,000 ft. deep generally yield calcium carbonate waters, moderate in total solids and in total hardness and distinguishable by their low sulphate content. These waters are suitable for domestic use, good or fair for irrigation, and fair or poor for boiler use. Many of them have been successfully applied to diversified crops for several years. Water from wells less than 50 ft. deep is generally poorer than that from slightly deeper wells. On the west side wells between the coast range and the trough of the valley yield hard, gypseous waters high in mineral content and especially in sulphate. Nearly all the waters taste of alkali, but they are potable except the most highly concentrated ones close to the foothills. The west-side waters are poorer for irrigation than those of the east side, but few of them are unfit for use if proper care is taken to prevent accumulation of alkali. . . .

"In the axis or trough of the valley wells yield waters distinguishable by the predominance of sodium and potassium among the basic radicles. . . . Nearly all except the salt waters and those from wells less than 300 ft. deep in or near the bed of Tulare Lake are potable. Many of those north of Kings River are poor for irrigation. . . . The deep artesian waters south of Kings River are good or fair for irrigation and for boiler use. Borings more than 1,200 ft. deep as far south as Fresno County yield strong salt waters unfit for use, but south of that county wells of that er greater depth yield sodium carbonate waters of low mineral content. Many flowing wells from 300 to 800

ft. deep in the axis also yield salt water. . . . The very deep waters of the east side and of the axis increase northward in mineral content, but the shallow waters show no such general relation."

Radio-activity of spring water, R. R. RAMSEY (*Proc. Ind. Acad. Sci., 1914, pp. 453-469, figs.* 7).—This is a description of methods and apparatus used in the determination of radio-activity in water. See also a previous report by the author (E. S. R., 34, p. 332).

Water supplies to rural and small urban areas, W. G. Savage (Jour. Roy. Sanit. Inst., 36 (1915), No. 9, pp. 365-381).—The author deals more especially with the sanitary side of small water supplies, calling attention to the results of his rather extended experience in judging the purity of water supplies, shallow wells in particular.

"It is evident that two distinct sources of pollution have to be guarded against—one the local contamination of the specific surface well, and the other the general contamination of the subsoil water. . . . If all surface wells were properly lined and made impervious to water for a depth of at least 12 ft., and were covered in to prevent pollution through the mouths of the wells, this would furnish a protection to the water quite sufficient for most country villages, unless the soil was very unsuitable for filtration purposes. . . .

"One common and widely held error is that a single water analysis, unfortified by local investigation, will enable an opinion to be given as to whether a supply is a pure one and fit for drinking purposes. . . . Water analyses only enable an opinion to be formed as to the condition of the sample submitted, and do not justify an opinion which covers the future purity of the supply. . . . The only satisfactory procedure is . . . to carefully examine the existing wells and any other sources of water supply, noting the accessibility, the depth of the subsoil water, its direction of flow (if possible), the relationship of the wells to the sources of contamination in their vicinity, the construction of the wells and how far they are built to keep out contaminating matters, the nature of the soil in which they are dug, the liability to flooding, the sufficiency of the water, and when liable to run out, etc. When this has been carried out, the wells which are best protected and from their surroundings least liable to contamination should be critically considered, and samples from these submitted for analysis to ascertain how far the subsoil water itself is polluted. With these some half-dozen samples should be sent for analysis from wells representing the average and worst conditions found from the topographical inspection."

Well waters from the trap area of western India, H. H. Mann (Dept. Agr. Bombay Bul. 74 (1915), pp. 66, pl. 1).—Analyses of a large number of samples of the well waters from different parts of the district are reported and discussed, with special reference to their uses for irrigation and domestic purposes.

A simple colloid-chemical process for removing micro-organisms from surface water in relation to drinking-water supplies in the field, M. Strell (München. Med. Wchnschr., 62 (1915), No. 34, pp. 1158, 1159, fig. 1; abs. in Chem. Abs., 9 (1915), No. 23, p. 3313).—In this process, a black, doughy mass called humin, giving a colloidal solution with water and prepared from brown coal by treatment with hot sodium hydroxid, is added to polluted water and the mixture is treated with the solution of a metal salt, forming a flocculent precipitate containing finely suspended substances like micro-organisms, dyes, native proteins, ec.

In experiments, river water containing 84,960 bacteria per cubic centimeter was treated with 10 per cent humin solution at the rate of 5 cc. per liter of water, and the mixture then received 10 per cent aluminum sulphate solution at the rate of 2.5 cc. per liter After sedimentation and filtration the filtrate was

found to contain from 4 to 8 bacteria per cubic centimeter. A repetition of the process removed practically all the bacteria. Filtration is said to be necessary as the process does not kill the bacteria. Canton flannel is recommended for filtration.

The activated-sludge process of sewage purification, G. J. Fowler (Surveyor, 49 (1916), No. 1255, pp. 148-151).—This is a summary of present knowledge of both the scientific and practical phases of the activated-sludge process of sewage purification, together with a list of 23 references to literature bearing on the subject.

Summary and latest results of experimental work on activated sludge at Milwaukee, Wisconsin, T. C. Hatton (Engin. and Contract.. 45 (1916), No. 5, pp. 104-108).—A summary of experiments conducted since the beginning of 1914 is given, from which the conclusion is drawn that "where a high and uniform standard effluent is required no other known process equals it either in first cost or cost of operation, and where the plant is of sufficient capacity to warrant the reduction of sludge to fertilizer the sludge problem becomes solved as never before possible."

Minth annual report of the state highway commissioner to the Governor of Virginia for the year ended September 30, 1915, G. P. COLEMAN (Ann. Rpt. Highway Comr. Va., 9 (1915), pp. 147, pls. 26, fig. 1).—This report deals, by counties, with road construction, expenditures, etc., in Virginia during the year ended September 30, 1915.

Methods of brick pavement construction (Good Roads, 49 (1916), No. 6, pp. 55-61, figs. 8).—Data obtained from inquiries addressed to a number of engineers on the so-called monolithic type of brick pavement are reported.

Forest Service proposes Douglas fir grading rule (Engin. Rec., 73 (1916), No. 7. pp. 212, 213, fig. 1).—A rule proposed by the Forest Service of this Department for grading Douglas fir timber for structural purposes is given. This follows the recent trend of yellow pine rules in placing in the first position clauses that determine the density of the timber. In addition to the visual inspection for density—by a rings-per-inch clause—the weighing of dried borings is provided for when the sticks do not meet the rings-per-inch rule. The plan of restricting knots, shakes, and checks in beams is also followed.

Gas tractors and their work, F. C. Perkins (Gas Engine, 18 (1916), Nos. 1, pp. 1-9, figs. 15; 2, pp. 61-67, 105, figs. 9).—The details of construction, operation, and control of some of the well-known makes of gas tractors are described, special attention being called to their advantages from the farmer's standpoint.

General notes on power farming, E. R. Wiggins (*Power Farming*, 25 (1916), No. 2, pp. 22, 44).—This paper gives information on the care of cooling systems, adjustment of farm gas engines, and use of the proper oil. Tests on four small gas engines are also reported, the purpose of which was to learn what may be expected of such engines of a given size and rating. The results are given in the following table:

Tests of small gas engines.

Rated borsepower.	Bore and stroke.	Revolu- tions per minute.	Piston speed per minute.	Maximum actual horse-power pulled.	Horse- power during test.	Gasoline perhorse- power- hour	Gasoline per horse- power of 10 hours.	Cooling water per 1) hours.
1.50 1.75 1.50 1.75	Inches. 3.75×5.0 3.50×5.0 3.50×4.0 4.00×4.5	500 550 500 450	Feet. 417 458 333 337	1. 63 1. 72 1. 17 2. 00	1. 48 1. 72 1. 00 1. 77	Pounds. 1. 01 . 85 1. 08 . 76	Gallons. 1. 62 1. 36 1. 70 1. 21	Gallons. 3, 70 6, 60 2, 50 2, 82

The adjustment and operation of engine plows, C. O. Reed (Amer. Thresherman, 18 (1916), No. 10, pp. 39, 40, 42, 43, figs. 7).—The author deals with free-lift and unit-lift gang plows, giving information in particular regarding adjustments in assembling for average conditions, the set of coulters, and hitch and side draft.

A homemade windmill, R. H. SMITH (Rural New Yorker, 75 (1916), Nos. 4363, p. 149, figs. 2; 4364, p. 181, figs. 2).—The details of a homemade wooden windmill are described and illustrated.

Harvesting grain in California: The combined harvester v. the grain binder, G. W. Hendry (Univ. Cal. Jour. Agr., 3 (1915), No. 4, pp. 129-137. pl. 1, fgs. 4).—Data resulting from experience at the experimental farm at Davis, Cal., are reported, which indicate that the net returns per acre in barley production, using the binder and stationary threshing machine, were \$7, against \$4.16 using the combined harvester. It is pointed out that the combined system has been a salient factor in reducing the cost of grain production, but at a great sacrifice in yield. "There is a growing sentiment among farmers that the binder system is a more economical system than the combined harvester system, as measured by the net returns per acre. [This] is manifested by the fact that the number of binders used in this State is constantly increasing."

Using the modern grain separator, G. F. Conner (Power Farming, 25 (1916), No. 2, p. 12).—The operation and use of the labor-saving attachments, including the feeders, wind stacker, grain handlers, and dust collectors, are dealt with.

The drinking of dairy stock and automatic watering devices, O. Felix (Schweiz. Arch. Tierheilk., 57 (1915), No. 12, pp. 651-666, figs. 2).—The importance of clean water supplies for dairy stock is pointed out, and some automatic watering devices to be used in stalls are briefly described as both convenient and sanitary.

Experiments with aluminum milk and dairy receptacles, A. Peter (Molk. Ztg. Berlin, 25 (1915), No. 47, pp. 369, 370; Jahresber. Molk. Schule Rütti-Zollikofen, 28 (1914-15), pp. 22-27).—Tests of aluminum cheese tubs, milk and dairy receptacles, milk cans, and milk bowls led to the conclusions that aluminum cheese tubs may be economically used when copper becomes relatively more expensive than aluminum and that aluminum is the material most to be recommended for large milk and dairy receptacles and for milk conveyors in dairies. Aluminum is also a good material for milk bowls, but this use and the use for cheese tubs cause trouble in cleaning the walls without injuring them. It is stated that the problem of a sufficiently resistant and durable aluminum milk can has yet to be solved.

Protective paints for metal, wood, canvas, and cement roofs, F. Schrader (*Mus. Landw. Ztg.*, 35 (1915), No. 55, pp. 364-366).—The proper materials and mixtures thereof for the different types of roof are pointed out.

Rural sanitation, W. B. GIVENS (Fresno [Cal.] State Normal School Bul. 3 (1915), pp. 14, figs. 4).—This briefly describes and illustrates the well-known Kentucky sanitary privy and a so-called septic tank of the multiple-chamber, continuous-flow type. The rather unusual statement is made that the tile drainage system below the tank should have a fall of from 4 to 6 in. per 100 ft. Departing further from usual practice the suggestion is made that "when the tank is completed and filled with water, five or six shovelfuls of well-rotted horse manure should be put into it to inoculate the fluid with the liquefying, purifying germs upon which everything depends."

RURAL ECONOMICS.

How the Department of Agriculture promotes organization in rural life, C. W. Thompson (U. S. Dept. Agr. Yearbook 1915, pp. 272a-272p).—This article gives a brief description of the activities of this Department in improving rural life through organizations, treating of the work in connection with the farm management investigations, boys' and girls' clubs, county organizations for extension activities, organizations for the introduction of special crops or for obtaining better seed, control of animal diseases, cow-testing associations, organizations for road improvement, work for improving market facilities, agricultural credit, and for the encouragement of social activities.

The author points out that "it may be noted that in every case the organization is undertaken for some specific purpose, and that that purpose is one which can better be accomplished through concerted effort than through individual action alone. This represents the general policy of the Department with regard to organization among farmers."

How Hawaii helps her farmers to market their produce, E. V. WILCOX (U. S. Dept. Agr. Yearbook 1915, pp. 131-146, pls. 2).—In this article is given a description of the market conditions in Hawaii and the efforts of the Hawaii Federal Experiment Station, through its marketing division, to find a market for the native produce. When the division first took up its work the town and city traders were purchasing very little native produce on account of the irregularity of receipts and lack of uniformity of packing. The marketing division sought out favorable producing centers for certain crops, taught the natives how to handle their produce, and established a market information service.

Results of this work are summarized as follows: "Starting with unorganized and isolated farming communities of different races, it has brought these men together to the mutual benefit of all concerned. Beginning with a farming population, which had been originally laborers and totally without information as to market requirements for farm products, it has brought about a striking improvement in the grading and packing of tropical fruits and products to the benefit of the farmer and of the consumer in Honolulu and on the mainland. Initiating a practical market system among a set of farmers who were thoroughly discouraged as to the prospects of carrying on general agriculture in Hawaii, it has shown that reasonable profits can be derived from diversified agriculture in Hawaii."

The cooperative purchase of farm supplies, C. E. BASSETT (U. S. Dept. Agr. Yearbook 1915, pp. 73-82, pl. 1).—The author enumerates as the objects of cooperative purchase associations the elimination of waste in conducting their business, the securing of high-grade goods, and the standardization of supplies by using the same kind of implements, packages, etc.

The type of organization recommended is a board of five or seven directors and a secretary who is to act as business manager. It is advised that each purchaser pay in addition to a small membership fee a slight excess of the cost of the goods to cover the expenses of conducting the business. In transacting the business the association may also be used as a clearing house for orders so as to obtain carload lots. However, the author considers that it is better to give the local dealer an opportunity to bid on the purchases.

Another method advocated is to deposit in a local bank the necessary cash or arrange for the proper credit. The certificate of deposit is forwarded with the order. If warehousing or manufacturing is undertaken by the association a skillful manager is required.

The author claims that the chances for success in conducting cooperative stores are not so numerous or as great as many imagine. They should be attempted only after a most careful survey of local conditions and then only when sufficient capital and high-grade management are available. In conducting such stores, goods may be sold to the members either at cost, plus office expenses, interest, etc., or at regular retail prices. The plan of selling by regular retail prices is preferred by many because it is less disturbing to local trade and at the end of the season the profits may be divided between the member and nonmember patrons in the form of dividends,

A successful rural cooperative laundry, C. H. Hanson (U. S. Dept. Agr. Yearbook 1915, pp. 189-194, pl. 1).—The author states that the organization of the cooperative laundry at Chatfield, Minn., is unique in that, although a separate corporation, the laundry and the creamery have the same officers. The laundry company is organized under the cooperative laws of the State and has been capitalized at \$5,000.

The creamery company owns the building, which it rents to the laundry company at \$10 per month, and supplies it with power and heat at the rate of about \$15 per month. The building is an addition to the creamery, 30 by 70 feet, costing about \$2,000. Between and joining the two buildings are the boiler, engine, and coal rooms. This arrangement is found convenient for the operators of both plants, reduces overhead expenses, prevents contamination of cream and butter from the laundry, and is economical of heat and power. A portion of the second story has been finished off for a lunch and rest room for the employees.

"The equipment is of the most modern type, . . . cost about \$3,000, is similar to that used in good city laundries, and is sufficient to turn out \$400 worth of work per week.

"The charges based on weight are 5 cts. per pound, which includes the ironing of all flat work, underwear, and stockings. . . . The average cost per week for the family washing has been \$1.05. Patronage is about equally divided between city and country. The laundry usually employs about 8 persons."

A graphic summary of American agriculture, M. SMITH, O. E. BAKER, and R. G. HAINSWORTH (U. S. Dept. Agr. Yearbook 1915, pp. 329-403, figs. 82).—These pages contain a series of graphs and maps based upon the returns of the U. S. Bureau of the Census and the Bureau of Crop Estimates of this Department, showing the geographic distribution and production of farm crops, number of farms, area of farm land, rural population, value of farm property, number of live stock, and live-stock products.

Some outstanding factors in profitable farming, J. S. Cates (U. S. Dept. Agr. Yearbook 1915, pp. 113-120, fig. 1).—This article contains the conclusions brought out in previous studies of the Office of Farm Management of this Department, which have been summarized as follows:

"The farming business which is of efficient size, and which is made up of diverse units, put together in such a way as to operate smoothly and well, with full employment of both labor and horse and machinery equipment, provided supervision is adequate and the enterprises making up the farm are selected wisely and are efficient, complies closely with the outstanding factors of profit. . . .

"A vast number of American farmers are making their homes on impoverished land and are practically without working capital. The outstanding factors in profitable farming, in such cases, consist in a study of what to do with what they already have. The factors of profit must be toned down to terms of expediency under existing conditions."

Unprofitable acres, J. C. McDowell (U. S. Dept. Agr. Yearbook 1915, pp. 147-154, pls. 4).—Among the causes for unprofitable acres are mentioned that the area cultivated by a farmer may be too small to give him profitable employment, or the area may be so large that the farmer can not cultivate the land to the best advantage; the holding of land capable of profitable agricultural use out of cultivation for land speculation; and the prohibitive cost or lack of capital to properly drain land or clear it of stumps, stones, etc.

The author summarizes his article as follows: "To meet the growing demand for farm products we must farm more acres or make each acre produce more. Land not now in farms should be made into farms, and unimproved land now in farms should be improved, only in so far as this can be done profitably."

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt. 2 (1916), No. 4, pp. 29-40, figs. 2).—This number estimates the condition of winter wheat and rye on April 1, the condition of farm animals on the same date and losses during the previous year, prices paid to producers of farm products, estimated farm value of important products on March 15 and April 1, range of prices of agricultural products at important markets, the final estimate of the United States beet sugar production, maple sugar and sirup production in Vermont, the production of important crops in the leading five States during 1913–1915, a special report on the condition of truck crops and the early potato crop, and miscellaneous data.

An estimate of the apples harvested by months showed that 3 per cent is harvested in June, 11 per cent in July, 15 per cent in August, 26 per cent in September, and 45 per cent in October.

An inquiry sent to flour mills and grain elevators is summarized as follows: Of the 1915 wheat crop, 14.4 per cent was unfit for milling and 7.3 per cent was used for feed. About 4 per cent is usually fed.

An inquiry into the causes and extent of live-stock losses indicated that the anual loss of cattle from disease amounts to \$177,750,000, swine \$66.466,000, and sheep \$21,184,000. The following table gives the percentage of loss by causes:

Estimated annua	l live-stock l	osses in the	United	States.	bu	causes.
-----------------	----------------	--------------	--------	---------	----	---------

Cause of losses.	Cattle.	Swine.	Sheep.
	Per cent.	Per cent.	Per cent.
Hog cholera Texas fever and cattle tick	0.0	48. 9	0. (
Tuberculosis	5. 9 10. 8	0. 0 2. 6	0.6
Contagious abortion	9. 2	0.9	2.0
Blackleg	15. 5	0. 0	0.

Exposure	12. 2	8, 2	22.
Insufficient or irregular feeding.	15.3	10.0	13.
Pre-atory animals Miscellaneous live-stock diseases	2. 4	1. 1	18.
ALSCENALEOUS ITVO SLOCK GISEASES	23.3	17.7	20.
Total	100.0	100.0	10).

Information is given concerning apple production and value, showing that there were 76.350,000 bbls. of apples produced in 1915, of which 49,487,000 were sold at an f. o. b. price of \$1.78 per barrel. A table is included showing the distribution by varieties.

A special inquiry as to the changes in value of farm lands indicates that the value of farm lands in the United States in 1915 was \$45.55 per acre, compared with \$40.85 for the year previous. The census reported the value of farm lands

in 1910 as \$32.40, and in 1900 as \$15.57 per acre. It is stated that the percentage increases in farm-land values since 1912 are as follows: North Atlantic States, 17 per cent; eastern part of North Central States, 20 per cent; western part of North Central States, 28 per cent; South Atlantic States, 23 per cent; South Central States, 25 per cent; far Western States, 34 per cent; entire United States, 25.7 per cent.

The production of durum wheat in Minnesota, North Dakota, and South Dakota, the States producing about 95 per cent of the entire crop of durum wheat, was 37,900,000 bu., with an average yield of 19.3 bu. per acre, and an average value per acre of \$20.77. The average yield for other types of wheat in the same States was 17.4 bu., and the average value, \$20.04.

AGRICULTURAL EDUCATION.

The development of the Philippine Islands, H. J. WATERS (Manila: Bureau of Printing, 1915, pp. 45).—This is a summary of the results of a personal study of the natural resources of the country, the development and work of the schools, and the agricultural practices of the people of the Philippine Islands.

The author briefly outlines the work of the six governmental agencies that are giving instruction in agriculture or engaged in agricultural development, viz, the bureaus of agriculture, education, forestry, and science, and the colleges of agriculture and veterinary medicine, indicating extensive duplication, some of which is deemed economical and justifiable and some unnecessary and wasteful. Recommendations are made for combining the work of these various agricultural agencies and correlating with it the work of the bureau of education, not so much upon the grounds of economy of administration as upon the broader grounds of greater efficiency.

He suggests that while the bureau of education conducts elaborate crop tests in all the provinces and is accumulating valuable data regarding the behavior of these crops under different conditions of soil and climate, this work should be inspected or studied by a representative of the agricultural institutions, not with any idea of controlling it but with a view of making it successful and most helpful to the school children and farmers. It is his opinion, on the other hand, that the bureau of education should not assume that knowledge of agriculture which would justify its officers in recommending a practice for any region or in putting such practice into effect through its schools and school gardens, as it is the function of the bureau and college of agriculture to shape the agricultural policies of the islands as definitely as it is that of the bureau of education to shape their educational policies.

As regards the college of agriculture the author finds the departments of botany and chemistry exceptionally well organized and officered and comparing favorably with those of the better colleges of the United States, but that in the practical subjects the college is not so far advanced. He believes that by adding two years of agriculture, viz, a strong and closely supervised course of five hours in farm practice in the first year of the curriculum and a full course in agriculture, dealing with the staple crops and laying emphasis upon plant judging and selection in the second year, and by giving three courses instead of two in animal husbandry, the course would be fairly well balanced for the present. He holds that no matter what is finally done regarding the merging of a part of the work of the college of agriculture with that of the bureau of agriculture, the duty of the college to do research work must be clearly recognized and the necessary funds provided.

Agricultural instruction in Surinam, J. J. Leys (Jour. Bd. Agr. Brtt. Guiana, 9 (1915), No. 1, pp. 11-14).—This is a description of two-year agricul-

tural courses of 40 weeks each, with a three-hour lecture a week, for young farmers and teachers. Theoretical instruction is given in chemistry, botany, zoology, and physics, and practical knowledge in the tilling of the soil, the use of agricultural tools, drainage, manuring, cattle rearing, dairy work, and the cultivation of agricultural plants adapted to local conditions. The minimum age at which pupils are admitted is 15 years.

Elementary courses were started in March and secondary courses in May, 1915. Agricultural instruction in Surinam is entirely separate from elementary education and is under the supervision of the director of agriculture.

Horticultural winter schools, H. R. Jung (Gartenflora, 65 (1916), No. 1-2, pp. 14-18).—To meet the need of better facilities for elementary horticultural instruction in Germany, the author recommends the establishment of horticultural winter schools in connection with the agricultural winter schools, and outlines suggested regulations, subject matter, and a weekly schedule of hours for such schools.

Report of the work of the School Garden Association in 1913 and 1914 (Ber. For. Skolehav. Virks. [Denmark], 1913-14, pp. 31, figs. 17).—This report contains a summary of the school garden work in Denmark in 1913 and 1914, followed by brief reports on the work of several of the 70 individual gardens now there.

Regulations for grants in aid of agricultural education and research in England and Wales, 1916-17 (London: Bd. of Agr. and Fisheries, 1915, pp. 22).—This pamphlet deals with the conditions under which grants are awarded through the Board of Agriculture and Fisheries from the Development Fund or parliamentary appropriations.

Second thousand answered questions in California agriculture, E. J. Wickson (San Francisco: Pacific Rural Press, 1916, pp. 254).—These questions and answers relate to fruit and vegetable growing, grains and forage crops, soils, fertilizers, irrigation, live stock and dairying, feeding animals, diseases of animals, poultry keeping, and pests and diseases of plants. The book is a sequel to One Thousand Questions in California Agriculture Answered (E. S. R., 31, p. 494), and avoids duplication of the preceding volume.

Elementary vocational agriculture for Maryland schools, E. A. MILLER (Md. Agr. Col. Bul., 12 (1915), No. 8, pp. 222, figs. 70).—This is the complete series of monthly publications, from September to May inclusive, setting forth lessons in elementary vocational agriculture, outlined after a monthly sequence plan, and adapted to the seasonal, agricultural, and school conditions of Maryland, of which the first issue has been noted (E. S. R., 33, p. 695). The lessons treat of the following subjects: The soil, crops, the orchard, vegetable, fruit, and flower gardening, poultry, dairying, farm animals, buildings for farm animals, farm accounts, insects, plant diseases, silage, rope—knots, hitches, and splices, nature study, school ground improvement, and management suggestions. Each lesson comprises classroom work, practical exercises consisting largely of club activities and home projects, suggested correlations, and references to the literature.

Extension course in soils for self-instructed classes in movable schools of agriculture, A. R. Whitson and H. B. Hendrick (U. S. Dept. Agr. Bul. 355 (1916), pp. 92).—This course is designed to aid agricultural colleges in their extension work and is intended for the use of small groups of farmers assembled as a class to study the subject in a systematic manner, with one of their number as leader. An entire day is to be consumed by each of the 12 lessons, the forenoon being devoted to the subject matter and reference work and the afternoon to the practical exercises outlined. Reference books, apparatus, and supplies are listed in an appendix.

Suggestions for school and home projects in agriculture, K. L. Hatch and W. F. Stewart (Bul. Univ. Wis., No. 757 (1916), pp. 30, figs. 6).—This bulletin contains an outline of the purpose, aims, scope, and method of practical projects in the study of elementary and secondary agriculture; suggested outlines for a series of projects in dairying and orcharding, developing from the simple to the complex and illustrating the logical sequence of projects, and including short, medium, and long-time projects; suggested titles for a series of projects in corn growing; and a classified list of suggested short, medium, and long-time projects.

Practical examples in dairy arithmetic, H. E. Ross, E. S. GUTHRIE, and W. W. Fisk (Cornell Reading Courses, 5 (1915), No. 98, pp. 24, figs. 4).—Specific examples are given to show the farmer and the factory man how various computations required in dairy practice are made. In many cases the problems are based on figures taken direct from creamery records.

How the whole county demonstrated, B. KNAPP and J. M. Jones (U. S. Dept. Agr. Yearbook 1915, pp. 225-248, pls. 2, figs. 2).—An account is given of the difficulties encountered, methods employed, and results accomplished by county demonstration agents in the evolution of the rural life of Christian County, Ky., and Culpeper County, Va.

The boys' pig club work, W. F. WARD (U. S. Dept. Agr. Yearbook 1915, pp. 173-188, pls. 6).—The author discusses the objects and plan and some results of pig club work, the financing and subsequent careers of club members, prizes awarded, exhibits at county and state fairs, the home curing of pork, and the beneficial influence of pig club work on the boy.

The poultry club work in the South, R. R. Slocum (U. S. Dept. Agr. Yearbook, 1915, pp. 195-200, pls. 3).—The objects and methods of poultry club work in the South, work of the poultry club agents, community breeding, school poultry flocks, growth of the work in three years, and some results are discussed.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1915 (U. S. Dept. Agr. Yearbook, 1915, pp. 616, pls. 76, figs. 96).—This contains the report of the Secretary of Agriculture, previously noted (E. S. R., 35, p. 94); 24 special articles abstracted elsewhere in this issue; and an appendix containing a directory of the agricultural colleges and experiment stations and the state officials in charge of agricultural work, and statistics of the principal crops, farm animals and their products, the federal meat inspection, estimated value of farm products, tonnage carried on railways, 1912–1914, imports and exports of agricultural products, rural and agricultural populations, number of persons engaged in agriculture and area of agriculture land in various countries, and the utilization of the National Forests.

Annual report of the director for the fiscal year ending June 30, 1915 (Delaware Sta. Bul. 111 (1916), pp. 31).—This contains the organization list and the report of the director on the work and publications of the station. It includes a financial statement for the fiscal year ended June 30, 1915.

Getting the most out of farming, D. Wallace (St. Paul, Minn.: Author, 1916, pp. 128).—"A selected list of publications, of value to the farmer and farmer's wife, available for free distribution by the government and state experiment stations."

What shall the farmer read? F. H. HALL (N. Y. Dept. Agr. Bul. 75 (1915), pp. 2559-2590).—A classified list of books for the farm library is given, together with a discussion of the subject.

NOTES

California University and Station.—Plans are nearing completion for Hilgard Hall, the new reinforced concrete building about to be built on the university campus at a cost of \$350,000, and a wing of the present agricultural building. This expense is to be defrayed from the proceeds of the \$1,800,000 of building bonds authorized by the people of California through approval of an initiative measure proposed by the alumni of the university. The other buildings being erected from this initiative bond issue are Benjamin Ide Wheeler Hall, a granite classroom building, to cost \$700,000, which will accommodate 3,500 students at one time, and will contain also 47 studies for professors and a lecture room seating 1,090 people; the first unit of a new group of permanent buildings for chemistry, this first building to cost \$160,000; the completion of the university library, on which \$850,000 has already been spent, and on which an additional \$525,000 is now to be expended; and a second unit for a central heating and power plant, to cost \$60,000, and to increase the supply of heat and light so as to provide for these new buildings.

A contract for about \$100,000 has been let for the new buildings at the citrus substation at Riverside. The principal building is to consist of a two-story and basement center, 154 by 57 feet, with one-story wings each 100 by 55 feet. This structure is to provide extensive laboratory and office facilities. The center is to be used for administration, the library, a lecture room, and laboratories for entomology, plant breeding, soils, and orchard management, and one of the wings for plant pathology and plant physiology and the other for agricultural chemistry.

A director's residence, barns, and other buildings are also being erected under a \$25,000 appropriation. About 125 acres have been planted to grain to test the uniformity of the soil of the new site, and about 10 acres have been set out to apricots and pears as a part of a series of experiments on the principles of pruning.

The last annual farm picnic at Davis was attended by about 16,000 people, this being about three times the number on any previous occasion.

Edward P. Van Duzee has resigned as instructor and assistant in entomology to accept an appointment as curator of the department of entomology of the California Academy of Sciences.

Illinois Station.—Dr. A. D. Emmett, assistant chief in animal nutrition, has accepted the position of research biological chemist with a commercial firm at Detroit, Michigan, beginning September 1.

Mississippi College.—W. H. Smith, state superintendent of education, has been appointed president, vice George R. Hightower, beginning September 15.

Montana College and Station.—Leave of absence, terminating June 1, 1917, has been granted to H. E. Morris, assistant botanist, and E. J. Quinn, assistant chemist, for advanced study. Dr. E. H. Riley, assistant professor of animal husbandry, has resigned to devote his entire time to the work of the State Stallion Registration Board. R. C. McChord, instructor in animal husbandry in Purdue University, has been appointed assistant professor of animal industry.

Dr. W. E. Joseph, associate animal husbandman at the Illinois University and Station, has been appointed assistant animal husbandman, vice R. R. Dodderidge, whose resigntion has been previously noted.

New York State College and Stations.—Owing to a veto by Governor Whitman of the legislative printing appropriation bill, carrying a lump fund of about \$200,000, no state appropriation for printing the station bulletins and reports is available. The Cornell and State stations have each been receiving about \$60,000 per annum from this fund. The veto followed a refusal by the legislature to itemize the objects of expenditure.

North Carolina Station,—A campaign to stimulate interest in building silos in the Piedmont section of the State has been begun. A campaign is also under way to induce the patrons of creameries to have their children compete for about \$800 worth of prizes offered by the creameries for the best set of herd records kept for the year beginning July 1. About 100 entries for this contest have been obtained.

The division of markets is assisting the potato growers of the northeast section of the State through a wire service inaugurated in cooperation with the Office of Markets and Rural Organization of this Department, a saving to these growers of several thousand dollars being estimated. A similar service is being rendered to the cantaloup growers in the Sandhill section around Laurinburg.

Ohio State University,—Dr. Jay B. Park has been appointed professor of farm crops. He was associated for two years with the department of agronomy at the Illinois Station, and since that time has been studying plant breeding at Harvard University, from which he received his doctor's degree this spring.

Alfred C. Hottes, instructor in floriculture in Cornell University, has been appointed assistant professor of horticulture. His special work will be the developing of courses in floriculture.

Oklahoma College.—James A. Wilson, a former director of the station, has been placed in charge of extension work, vice W. D. Bentley, resigned to accept an appointment with the Office of Extension Work in the South, of the State Relations Service of this Department.

Hampton Institute.—R. W. Crouse and Louis Martin, instructors in agriculture, resigned July 1, the former to manage a farm in Iowa, and the latter to take charge of demonstration work among the negroes in Maryland. Dr. R. R. Clark, veterinarian and instructor in animal industry, resigned August 1 to become principal of the Theodore N. Vail Agricultural School at Lyndon, Vermont. J. L. B. Buck and A. E. Shipley, assistant and secretary to the director, have been given indefinite leave of absence for service in the Army in connection with the Mexican situation. Recent appointments include Floyd Crouse, J. R. Case, and J. M. MacIntosh, 1916 graduates respectively of the Iowa, Connecticut, and Ontario colleges, as instructors in farm crops, elementary agriculture, and farm physics.

Vermont University.—Miss Josephine A. Marshall, assistant professor of home economics, has accepted a position with Teachers' College of Columbia University.

Agriculture at the National Education Association.—According to The American Review of Reviews, the association "has not often given so much of its time to the country school and rural conditions as it did this year." At the meeting held at New York City, July 1 to 8, the fundamental line of thought in several departments was that the country school of all rural social institutions makes the best and most available center for rebuilding the rural community, and bears at present the greatest responsibility for socializing country life. The address of the president, Dr. David B. Johnson, of South Carolina, was

a plea for a national commission to study the farm home and the farm woman, and a resolution requesting President Wilson to appoint such a commission was adopted by the association.

In a paper before the Department of Rural and Agricultural Education, M. C. Burritt, state leader of farm bureaus for New York, enumerated as among the fundamentals in agricultural extension to-day the following: (1) Local responsibility for and partnership in any plan for the education of adult farmers and the development and organization of rural communities is essential. This may be obtained through a county farmers' association which has joint power and responsibility with the representative of the agricultural college in the management of the work. (2) The most efficient way to work in a specific community is through a community group and through local workers, as through a county advisory council with representatives in each community. (3) If the work is to be permanent, local initiative must be encouraged and developed and local leadership further trained and connected up with individuals of organizations in such a way that the work will be continuous and effective. This may also be done through the advisory council. (4) Experience indicates that the most effective method of teaching the best agricultural science, practice and organization, is that of the "demonstration." This is worked out in the farm bureau movement in New York State through local cooperators and the advisory council.

Field Exercises in Their Relation to Agricultural Teaching was the title of a paper by K. C. Davis, in which he maintained that agriculture must be kept a practical subject. Although agriculture is founded on both practice and science, he held that there is danger that in an effort to make agriculture a culture subject many schools will fail to maintain the practical side. The more practical phases may be given to the students through field exercises with soils, crops, orchards, live stock, machinery, etc., and through laboratory exercises, school and home demonstrations, and school and home projects. When the values of these methods of training and instruction are neglected the instruction may become too theoretical and too abstract and receive the criticism of being bookish. The paper suggested many concrete examples of field exercises, among them the identification of annual weeds in cultivated fields, making a school collection of ripe weed seeds, laying out drainage lines, collecting and studying nodules on roots of legumes, mapping, replanning, and remapping the farm, determining the expense for extra fencing on a poorly planned farm, comparing several farms with reference to methods or places for starting fruits, root crops, corn, small grain, and other staple products, and comparing farms in regard to the benefits of shrubbery, vines, and flowers used in beautifying the grounds.

L. H. Dennis spoke on The Home Project in Secondary School Agriculture, concluding that "the home project is an integral part of the scheme to furnish specific preparation for life on the farm. . . . To eliminate the home project from the vocational agricultural course would be equivalent to removing the means whereby theory and practice meet. While the home project idea has already been extensively developed, its possibilities have by no means been exhausted."

E. M. Tuttle described Rural School Extension Work by the New York State College of Agriculture. This now embraces the department of rural education, the publication of the Cornell Rural School Leaflet, and the junior home project work, begun within the past year, and directed exclusively by the educational authorities with the cooperation of other agencies.

Officers of this department of the association elected for the ensuing year include W. H. French, Michigan Agricultural College, president; Z. M. Smith,

Indiana State Department of Public Instruction, vice-president; and C. II. Lane, U. S. Department of Agriculture, secretary.

Among the organizations meeting with the National Education Association was the School Garden Association of America. The Relation Between School Gardens and Home Gardens was considered by L. A. DeWolfe, who reported that in Nova Scotia the school garden has not yet helped the home garden so much as it should since the school garden is still too often regarded as unnecessary or even detrimental to school work. "Nevertheless, the school garden has its place. It is the demonstration ground where principles to be applied to the home garden are taught. When the children see celery planted, or proper transplanting done, they can go home and do likewise. But no amount of telling will give them the courage to try."

In the paper by Caro Miller entitled Gardening in the City Schools of Tomorrow, she said that the formal restricted school gardening of yesterday and to-day is gradually giving way to a broader treatment of gardening from the standpoint of a vocation and an avocation.

"We may expect gardening in the city schools of to-morrow to develop along these lines: (1) Systematic training of all city normal school students in the theory and practice of gardening, (2) the widest use of the formal school garden through the school day by visiting classes, from the kindergarten to eighth grade, for practical work on a class plat and theoretical lessons from a progressive graded course of study, (3) home gardens supervised by paid trained teachers after school and during vacation, (4) vacant lots used as supplements to home gardens, (5) agricultural clubs for home project work, (6) well-organized fall exhibits of home and school garden products, (7) decorative plantings on school grounds which shall be truly a model for the neighborhood, (8) systematic planting and expert care of trees and vines for all schools, and (9) elective courses in general agriculture and horticulture offered in all high schools."

S. B. McCready read a paper on Ideal Gardens for Country Schools. He pointed out that ideal gardens presuppose ideal conditions, such as a permanent teacher interested in her community and believing in the power to affect human lives through gardening; an interested community intent on progress, loyal to their teacher and realizing that in the interests awakened in their boys and girls lie their best satisfactions; a loyal band of boys and girls not afraid of work, willing and desirous to help make the school attractive; and a school property worth improving and possible to improve, having good soil, etc.

Ellen Eddy Shaw read a paper on What Can a Botanic Garden Do to Help School Gardens? This consisted largely of a review of the work of the Brooklyn Botanic Gardens through regular garden instruction, cooperation with the schools in their nature and geography work, and courses given to teachers in garden work and in botanical nature work.

Association of Agricultural College Editors.—This association met for its fourth conference at the Kansas College, June 21–23, with representatives of about fifteen States and this Department. An address of welcome was given by President H. J. Waters, in which he advocated as the ideal qualification for college editors, training in agriculture and journalism, together with newspaper and farm experience. An exhibit of bulletins and press material formed a special feature of this meeting.

Officers were elected as follows: President, W. C. McClintock, director of publications in the Ohio State University; vice-president, N. A. Crawford, professor of industrial journalism in the Kansas College; secretary-treasurer, Dr. B. E. Powell, director of information in the University of Illinois; and additional members of the executive committee, H. B. Potter and W. C. Palmer,

editors respectively of the University of Tennessee and the North Dakota College.

Federal Aid in Rural Post Road Construction.—An act approved July 11 authorizes the Secretary of Agriculture to cooperate with the States through their highway departments in the construction of rural post roads. An appropriation of \$5,000,000 is made for the fiscal year ending June 30, 1917, \$10,000,000 for 1918, \$15,000,000 for 1919, \$20,000,000 for 1920, and \$25,000,000 for 1921, to carry out the Act. Not to exceed three per cent of the appropriation for a year may be used for administrative purposes, and the remainder is to be apportioned among the States. The basis of apportionment is as follows: One-third in the ratio which the area of the State bears to the total area; one-third in the corresponding ratio as to population; and one-third in the ratio which the mileage of rural delivery and star mail routes in a State bears to the total mileage on such routes.

Projects must be submitted to the Secretary of Agriculture for all roads to be constructed, and upon his approval not to exceed fifty per cent of the cost may be expended as the share of the Federal Government. Construction is to be under the supervision of the state highway departments, but subject to the inspection and approval of the Department. The States must maintain all roads constructed under the Act, and may be debarred from further participation in its benefits until roads have been put in proper condition.

An appropriation for \$1,000,000 per annum for ten years is also made available for the construction of roads and trails wholly or partly within the National Forests. These roads will subsequently be maintained upon a cooperative basis. Expenditures under this provision are to be reimbursed from the revenues of the National Fôrests.

Cooperation with the United States Department of Agriculture.—A recent issue of the Weekly News Letter announces that nearly 770,000 persons are now alding this Department as cooperators without compensation. This service is being rendered mainly by furnishing information, demonstrating the local usefulness of new methods, and the like. There are also 4,560 weather observers, 15,000 railroad agents reporting shipments of perishable crops to be used in the market news service, and many other trade agencies. It is estimated that at least one farm in every twenty is working in some way with the Department, and thousands of others are rendering similar service to the agricultural colleges and experiment stations.

Miscellaneous.—A tablet, presented by the Guernsey Breeders' Association, was unveiled June 20 at the University of Pennsylvania in memory of the late Dr. Leonard Pearson, formerly professor in the university veterinary school and dean of the faculty.

The Yorkshire Agricultural Union has decided to raise a national fund for the representation of agriculture in the British Parliament by practical farmers. The Cresson Types of Hymenoptera, by Ezra Townsend Cresson, constitutes No. 1 of the Memoirs of the American Entomological Society.

No. 3.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Annual reports on the progress of chemistry for 1915, edited by J. C. CAIN, A. J. GREENAWAY, and C. SMITH (Ann. Rpts. Prog. Chem. [London], 12 (1915), pp. VIII+268, figs. 6).—This report deals with the progress made during the year 1915 in the subjects listed in reports previously noted (E. S. R., 35, p. 8).

The preparation and composition of caseinogen, J. Mellanby (*Biochem. Jour.*, 9 (1915), No. 3, pp. 342–350).—The author uses the word caseinogen to denote the main protein present in milk; acidic caseinogen, the protein precipitated from milk by acid; and casein, the protein precipitated from milk by the action of proteolytic ferments and calcium salts.

A method for the precipitation of caseinogen from milk by alcohol is described in detail, together with experimental data as to the calcium and phosphorus content of caseinogen and of acidic caseinogen.

The results of the analyses of caseinogen and acidic caseinogen indicate that caseinogen is composed of a complex of one unit of protein and a molecule of tricalcium phosphate. The precipitation of acidic caseinogen from caseinogen by acetic acid is expressed by the formula

Protein, Ca_3 (PO₄)₂+6H \overline{A} =Protein, 6H \overline{A} + Ca_5 (PO₄)₂ (caseinogen) (acidic caseinogen).

A note on iodized protein, A. Oswald (Hoppe-Seyler's Zischr. Physiol. Chem., 95 (1915), No. 5-6, pp. 351, 352).—The author describes a procedure for the preparation of an iodized casein. This contains 14.39 per cent iodin, is pure white in color, and is not affected by the action of even the direct rays of sunlight.

A colorimetric method for the estimation of amino-acid α-nitrogen.—II, Application to the hydrolysis of proteins by pancreatic enzyms, V. J. Harding and R. M. MacLean (Jour. Biol. Chem., 24 (1916), No. 4, pp. 503-517, figs. δ).—The colorimetric method previously described (E. S. R., 34, p. 505) has been experimentally applied to a study of the rate of proteoclasis of casein, serum albumin and globulin, peptone, nucleoprotein, gluten, fibrin, and gelatin by pancreatic enzyms. The results were compared with those obtained by the Sörensen and Van Slyke methods, and agreed very well with those from the Van Slyke but not from the Sörensen method.

The composition of "lecithin," together with observations on the distribution of phosphatids in the tissues and methods for their extraction and purification, H. MacLean (Biochem. Jour., 9 (1915), No. 3, pp. 351-378).—Phosphatids extracted from tissues by alcohol invariably contain large amounts of a nitrogenous impurity which is very difficult to remove by any of the

ordinary methods of preparation. This material is very complex chemically and contains bodies of a purin nature. All the nitrogen of lecithin is accounted for by the cholin and amino nitrogen present.

By fractionation of the cadmium chlorid salt lecithin can be separated into two components (true lecithin and kephalin). True lecithin contains all of its nitrogen in the form of cholin, while the kephalin fraction contains only a part as cholin and the greater part as amino-ethyl alcohol.

Procedures for the extraction and purification of the phosphatids and also for the determination of cholin are discussed.

On certain constituents of the germinating maize, E. Winterstein and F. Wünsche (Hoppe-Seyler's Ztschr. Physiol. Chem., 95 (1915), No. 5-6, pp. 310-336).—Experimental results have shown that the constituents of the germinating maize are, in many respects, different from those of the germinating wheat. The crystalline nitrogenous substances (protein cleavage products) isolated from the germinating wheat could not be found in the maize.

In the two samples examined no arginin could be isolated and only traces of glutamin. Guanidin, however, was found to be present, together with a base of unknown constitution. Hordenin (parahydroxyphenylethylamin) was also found in the maize embryo. It is possible that the amino acids carried to the maize embryo are used immediately in constructing the protein mole cule, while in the wheat embryo there is a partial accumulation of these products. Whether or not the guanidin is found as an intermediate product of the protein synthesis is doubtful.

It is of interest to note that in the autolysis of the maize embryo in vitro only a small amount of protein cleavage is apparent. In the hydrolysis of the isolated proteins the usual amino acids were found. A large amount of water-soluble protein with a small amount of globulin constituted the protein found in the maize embryo. No nucleic acid could be isolated.

The fat content of the maize was found to be about four times as great as that of the wheat. The fat contained solid and liquid fatty acids, together with sitosterin and phosphatids.

A glucosid was also found, together with pentoses which were probably split from pentosans during the autolysis, and a considerable amount of inosit phosphoric acid.

The occurrence of sucrose in grapes of American origin, H. C. Gore (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 333, 334).—An examination of 66 varieties of American grapes during four successive seasons showed that 43 of them contained no sucrose, 10 contained sucrose occasionally, and in 13 varieties it was frequently present.

It is indicated that sucrose should be regarded as a normal constituent of many varieties of grapes of American origin.

The occurrence of sucrose in relatively large amounts in a new seedling grape, W. B. Alwood and J. R. Eoff, Jr. (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 334, 335).—The authors submit analytical data of a seedling grape of unknown origin in various conditions. The data include the specific gravity, total solids, sugar-free solids, invert sugar, sucrose by inversion, total sugar as invert, and total acid as tartaric.

The acetone content of milk, N. O. Engreldt (Hoppe-Seyler's Ztschr. Physiol. Chem., 95 (1915), No. 5-6, pp. 337-350).—A summary of the analytical data submitted shows the acetone content of cow's milk to vary between 1.45 and 2.42 mg. per liter, with an average of 1.85 mg. for ten determinations. The total quantity per day varied, and seemed to be in direct relation to the quantity of milk produced. The age of the animal, the stage of lactation, and

the conditions of pregnancy seemed to have no influence on the acetone content of the milk.

The quantity present in mare's milk varied between 0.48 and 0.97 mg, with an average of 0.71 mg, per liter in five determinations. In ewe's milk for five determinations the variation was found to be between 0.48 and 0.68 mg,, with an average of 0.56 mg, per liter. The amount in goat's milk varied from 0.97 to 1.45 mg,, with an average of 1.07 mg, per liter for six determinations. Unilateral thyroidectomy had no influence on the acctone content of the milk. In human milk the variations were found to be between 0.48 and 1.16 mg, per liter.

The procedure used by the author for the determination of the acetone was to precipitate the protein of the milk with a 10 per cent solution of tannic acid, then distill the acetone in the usual manner, and titrate with a standard iodin solution, using a finely calibrated burette.

Studies on the reducing properties of milk, J. Samšula (Wiener Tierürztl. Monatsschr., 2 (1915), No. 12, pp. 545-552).—The author has repeatedly observed that if two samples of middle milk are drawn from any quarter of the udder of a healthy cow, the one in a sterile container and the other simply in a clean container, both samples will decolorize methylene blue in the same period of time. After being kept at room temperature, however, for about eight hours the sterile sample will decolorize methylene blue much sooner than the other sample. The difference in time of decolorization is considerable and not easily explained.

It is indicated that the bactericidal property of milk probably plays a rôle in the phenomenon, and that by its activity it destroys the reducing enzym.

The analysis of waxes with special reference to beeswax and wool wax, F. W. RICHARDSON and G. A. BRACEWELL (Jour. Soc. Chem. Indus., 35 (1916), No. 3, pp. 160-163).—The following average values, obtained from the analyses of three samples of beeswax, are submitted: Unsaponifiable matter—Hübl iodin value, 8.06; butryo-refractometer at 75° C., 21.3; refractive index at 75°, 1.4386. Saponifiable matter—melting point, 53.9°; butryo-refractometer at 50°, 31.1; refractive index at 50°, 1.446; calculated butryo-refractometer at 75°, 15.6; Hübl iodin value, 11.9.

The average composition of wool wax obtained is given as follows: Saponifiable matter—free fatty acids, 2 per cent; neutral esters, 56 per cent. Unsaponifiable matter—42 per cent. The wax itself has the following values: Hübl iodin value, 25; acid value, 4; butyro-refractometer at 50°, 76. Fatty acids in the saponifiable matter: Hübl iodin value, from 8.5 to 10; melting point, 42°; butyro-refractometer at 50°, 45; neutralization value, from 136 to 150. The unsaponifiable matter has a refractive index of from 1.489 to 1.495, Hübl iodin value of from 40 to 50, and acetyl saponification value of 135.

The analytical procedures used in separating the saponifiable and unsaponifiable matter are outlined in detail. Other analytical methods are also described.

Researches on the nature of enzym action.—IV, The action of insoluble enzyms, W. M. Bayliss (Jour. Physiol., 50 (1915), No. 2, pp. 85-94).—Continuing work previously noted on the nature of enzym action (E. S. R., 31, p. 608), it has been shown that urease, lipase, emulsin, invertase, lactase, papain, peroxidase, and catalase are active in media from which they can be filtered by ordinary filter paper, while the filtrates are inactive. Suspensions of solid preparations of pepsin and trypsin in strong alcohol are decidedly more active than the filtrates of such saturated solutions. These enzyms seem to be able to assume a colloidal state in such solutions to a small degree and thus to exhibit a slight activity.

"Enzymic activity is thus manifested at the interface of contact between the solid enzym phase and the liquid substrate phase. The catalysts concerned are not in true solution."

I, The relation of hydrogen ion concentration of media to the proteolytic activity of Bacillus subtilis. II, Proteolysis of Streptococcus erysipelatis and S. lacticus compared under different hydrogen ion concentration, A. Itano (Massachusetts Sta. Bul. 167 (1916), pp. 139–185, figs. 6).—The bacteriological value of Sörensen's method for the study of proteolysis in conjunction with variations in the hydrogen ion concentration has been determined, the organism B. subtilis being used in the investigation. It was shown that certain hydrogen ion concentrations measure the exact influence, both inhibitory and prohibitory, and indicate the exact limits of the proteolytic activity of the micro-organism. With increasing proteolysis the hydrogen ion concentration of the medium converges toward the optimum. The results indicate that B. subtilis produces endoenzym and no exoenzym. Sörensen's method yielded very satisfactory results in determining the rate of proteolysis. For obtaining any desired hydrogen ion concentration in a medium the colorimetric method was used.

The apparatus and technique employed in the investigation are described in detail. A review of the earlier literature on the subject is also included.

Part 2 deals with the application of the method developed in the investigation to a study of *S. crysipelatis* and *S. lacticus*. The virulent strain of *S. erysipelatis* was found to multiply much more rapidly in a broth medium than the nonvirulent strain, *S. lacticus*. A difference both in degree and rate of proteolysis was evident, *S. crysipelatis* being much more active and vigorous. The results indicate a very close relationship between the optimum hydrogen ion concentration for proteolysis (in the bouillon) and the hydrogen ion concentration of the natural environment of the organisms (blood and milk).

The general applicability of the paper pulp filter to quantitative analysis, S. L. Jodde and E. H. Kellogg (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 317-319).—Experimental data submitted indicate that the application of the pulp filter to the quantitative estimation of barium and sulphuric acid as barium sulphate, of silver and hydrochloric acid as silver chlorid, and of potassium and ammonium as chloroplatinate gives results as accurate as those obtained by the use of standard filter paper. See also a previous note (E. S. R., 34, p. 712).

A simple apparatus for filtration under diminished pressure, J. C. IRVINE (Biochem. Jour., 9 (1915), No. 3, pp. 321, 322, fig. 1).—An apparatus is described in which a specially designed cylindrical tube is used instead of an ordinary suction flask for filtration under diminished pressure. The apparatus is deemed of special value when manipulating small quantities of material in that it obviates undue loss in transferring the material to another container.

Color standards and colorimetric assays, H. V. Arny and C. H. Ring (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 309-317).—The preparation of color standards for ammonia, nitrate, nitrite, vanillin, uric-acid, salicylic-acid, and phosphate colorimetric procedures is described in detail. The solutions used for making standard blends are divided into three series, viz, cobalt-iron-copper, cobalt-chromium-copper, and chromium-manganate.

Some indicators from animal tissues, W. J. CROZIER (Jour. Biol. Chem., 24 (1916), No. 4, pp. 443-445).—The preparation and color changes of indicators prepared from Ascidia atra, Ptychodera sp., Chromodoris zebra, and Eupolymnia aurantiaca (?) are reported.

The influence of fluorspar on the solubility of basic slag in citric acid, G. S. Robertson (Jour. Soc. Chem. Indus., 35 (1916), No. 4, pp. 216, 217).—Experimental data submitted indicate that the citric-acid test gives no true

index of the phosphate present in fluorspar slags and affords no guide as to the value of the slag. The phosphatic slag obtained by the use of fluorspar in the manufacture of steel by the open-hearth process has a low citric-acid solubility. The phosphate is, however, completely soluble if the extraction be prolonged for a sufficient time. The phosphates in the slag do not appear to be in combination with silica, but seem to bear a close resemblance to those contained in mineral phosphates.

Improved methods for fat analysis, E. B. Holland, J. C. Reed, and J. P. Buckley (Massachusetts Sta. Bul. 166 (1915), pp. 91-138, figs. 4).—This bulletin outlines the methods for determining the various chemical constants of oils, fats, and waxes. The methods have been carefully studied and many improvements both in the apparatus and technique introduced. Tabulated data and supplementary notes of value in the interpretation of analytical results, together with formulas for calculating certain other constants, are included.

A new procedure for the determination of the acetyl number is described as follows: Into a 300 cc. Erlenmeyer flask are brought 5 gm. of fat together with 10 cc. of acetic anhydrid. The flask is connected with a spiral or other form of reflux condenser and heated in a boiling water bath for from 1 to 1.5 After acetylating, the condenser is removed from the flask and sufficient ceresine added to form a solid disk with the fat when chilled in cold water. With the flask still in the water bath 150 cc. of boiling water is added, with as little disturbance of the fat layer as possible. The flask is then removed and the contents rotated vigorously to dissolve occluded acetic acid. The ceresine fat is then solidified by immersing the flask in cold water, after which the solution is decanted through a dense filter, care being taken not to break the insoluble cake. Another 150 cc. of boiling water is added, thoroughly agitated, heated a few minutes in the bath, cooled, and decanted. The process is repeated until the final filtrate gives a decided color with two or three drops of tenth-normal alkali, using phenolphthalein as indicator. filter and inverted flask containing the cake of ceresine fat are allowed to drain in a cool place until practically dry. The small particles adhering to the filter are then scraped into the flask, the inner portion of the filter paper extracted in a small beaker with three successive 20 cc. portions of boiling alcohol, and poured into the flask. Fifty cc. of alcoholic potash and several glass beads are then added, the flask is connected with a suitable form of reflux condenser, and the solution boiled on the water bath until saponification is complete. After cooling the solution to 60° C. it is titrated with halfnormal hydrochloric acid, using 1 cc. of phenolphthalein or cotton blue, as indi-The alcoholic mixture is again brought to boil to free any alkali occluded in the ceresine, and retitered if necessary. Several blank determinations should be run with every series of tests, under precisely similar conditions as to time and treatment except that the ceresine may be omitted. Every lot of ceresine, however, must be tested and be free from soluble matter and not assimilate any alkali on saponification. The difference between the titration of the blanks and that of the excess alkali in the test is the acid equivalent of the fat after acetylation, which is calculated to milligrams of potassium hydroxid per gram of fat.

For the determination of unsaponifiable matter the following modified procedure is described: Five gm. of fat are completely saponified in a 300 cc. Erlenmeyer flask with 75 cc. of alcoholic potash and 25 cc. of alcohol under a reflux condenser. The solution is then transferred to a 250 cc. Griffin beaker and the flask rinsed several times with hot alcohol. The alcohol is evaporated

in a water bath at a gradually increasing temperature. Several 25 cc. portions of methyl alcohol are added and evaporated to insure dryness. The dry residue is then pulverized in a mortar with 25 gm. of anhydrous potassium carbonate, dried 2 hours at 100°, transferred to an S. & S. extraction thimble, extracted from 2 to 3 hours with anhydrous ether in a continuous extractor, and the ether distilled off as usual. Any trace of moisture absorbed during the process will contaminate the ether extract with a small amount of water-soluble compounds. To eliminate this error the air-dried extract is washed with several 25 cc. portions of water at room temperature, decanted on an ether-extracted filter which is air-dried, and extracted with ether, using the same flask as before. The purified extract is dried from 1 to 1.5 hours in an oven at 100° and considered as unsaponifiable matter. This procedure is not applicable for volatile hydrocarbons or ethereal oils.

The use of enzyms and special yeasts in carbohydrate analysis, W. A. Davis (Jour. Soc. Chem. Indus., 35 (1916), No. 4, pp. 201-210, fig. 1).—Methods for the determination of saccharose, raffinose, maltose, and starch in plants and their products by means of enzyms are described in detail. On account of the specificity of the enzym action it is indicated that such methods are of especial value in estimating the individual constituents of a complex mixture of carbohydrates.

On the determination of reducing sugars in the presence of an excess of sucrose, L. MAQUENNE (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 6, pp. 207-213).—The influence of large amounts of sucrose on the determination of reducing sugars has been studied in some detail and the results of the investigation reported.

The temperature at which the reduction takes place and also the time of heating exercises a marked influence on the results for the reducing sugars. Heating for 10 minutes at 65° C. is recommended as yielding the best results. The quantity of sample used in the analysis is also important. For materials poor in invert sugar 20 gm. samples are recommended.

The hyposulphite titration has been slightly modified and used with excellent results, especially for very small amounts of copper. The procedure, however, is not applicable in the analysis of molasses and similar materials which contain substances that absorb iodin. For such material the copper oxid must be determined either gravimetrically or by some other volumetric procedure.

An apparatus for digesting crude fiber, J. M. Pickel (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 366, 367, figs. 2).—A simple form of condenser for use in crude fiber determinations which is easy to manipulate is described in detail. The form and construction of the condenser obviates the use of all rubber connections. It can be made of zinc, copper, or even glass. In the latter case an ordinary glass flask provided with a suitable side tube in its neck is quite satisfactory.

A furnace for crude fiber incineration, J. M. PICKEL (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 367, fig. 1).—An inexpensive and easily constructed furnace for use in crude fiber determinations is described in detail. It consists of a piece of asbestos board with a circular opening upon which is set a disk of wrought iron. An asbestos cylinder, specially prepared, is placed around the iron disk and is covered with a piece of asbestos board of the same dimensions as that of the base, having a small hole in its center. The heat is supplied by a small Bunsen burner.

The analysis of maple products.—VII, The electrical conductivity test for purity of maple sirup, J. F. SNELL (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 331-333).—Revised directions for the conductivity test of maple sirup previously noted (E. S. R., 31, p. 610) are submitted.

Genuine sirups have shown conductivity values as low as 96 and as high as 230. The limits of percentage variation of the conductivity value in genuine sirups are much narrower than those of any of the older analytical values, but not so narrow as those of the volumetric lead number. Additional analytical data on nonmaple sirups are reported.

A comparison of methods for the determination of casein in milk, C. B. Hersey (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 335, 336).—Although the official nitrogen method is the standard of accuracy for the determination of casein in milk, the analytical results obtained show that the Hart method (E. S. R., 19, p. 707) with electric centrifuge is dependable, checking very closely the official method. It is deemed far superior to the volumetric method of Van Slyke and Bosworth (E. S. R., 22, p. 112).

The Hart method possesses the advantages of requiring only a very little time and neither exactly standard solutions nor final calculation of results.

The occurrence and determination of creatin in the urine, F. H. McCeuden and C. S. Sargent (Jour. Biol. Chem., 24 (1916), No. 4, pp. 423-429).— Experimental data submitted indicate that "human urine contains a substance or substances other than creatin which can give a color reaction similar to that of creatinin on boiling with picric acid, and which, therefore, may appear in the results as creatin."

The reduction of As₅ to As₅ by cuprous chlorid and the determination of arsenic by distillation as arsenic trichlorid, R. C. ROABK and C. C. McDonnell (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 327-331, fig. 1).— Experimental data indicate that ferrous salts effect only an incomplete reduction of As₅ to As₅ in hydrochloric-acid solutions. Satisfactory results can be obtained only under certain conditions, usually with the presence of a small amount of copper which forms cuprous chlorid, or when only very small amounts of arsenic are present. Cuprous chlorid effectively reduces the arsenic in hydrochloric-acid solution and completely separates the arsenic trichlorid from antimony, lead, copper, zinc, iron, and calcium.

The method described consists of distilling a sample of the insecticide or fungicide in a hydrochloric-acid solution with cuprous chlorid and, after neutralization of the distillate, titrating the arsenic with standard iodin solution.

New methods for the analysis of lime-sulphur solutions.—II, The estimation of "polysulphur," R. M. Chapin (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 339-341).—In continuation of the work previously noted (E. S. R., 34, p. 806), the author has developed a new method for the estimation of polysulphur which is claimed to be both accurate and convenient.

The method, briefly outlined, consists of adding 10 cc. of a dilution of the sample to 10 cc. of a recently prepared 10 per cent solution of C. P. anhydrous sodium sulphite and 20 cc. of fifth-normal ammoniacal zinc chlorid contained in a 200 cc. Erlenmeyer flask. Twenty-five cc. of water is added and the mixture placed on the steam bath. At intervals of 10 minutes the contents of the flask are agitated and the material adhering to the sides of the flask rinsed down with a little hot water from a wash bottle. After heating for 45 minutes, with four intermediate mixings, the flask is removed from the water bath and 20 cc. of a 10 per cent solution of crystallized strontium chlorid added. The mixture is allowed to settle for 5 minutes and filtered into a 250 cc. volumetric flask and the precipitate washed with hot water. The clear liquid is then cooled to room temperature and from 0.5 to 1 cc. of a 10 per cent solution of crystallized disodium phosphate added, made to the mark, well shaken, and filtered through a dry paper into a dry flask, the first portions being used to thoroughly wet the paper, and the runnings discarded. To 200 cc. of this clear filtrate methyl red is added and then, slowly, with thorough mixing, a 10 per cent solution of

tartaric acid to a permanent slight acid reaction. Starch is now added, and the liquid titrated with tenth-normal iodin.

From the titration figures obtained from this procedure and those previously described the various forms of sulphur existing in the dilute lime-sulphur solution can be calculated by formulas which are submitted. Suggestions on the execution of the proposed method are discussed in detail.

It is concluded that "the use of a single standard solution which can be so easily and accurately prepared and used as tenth-normal iodin means a possibility of increased accuracy, as well as a saving of time, over the gravimetric estimation of sulphur as barium sulphate under conditions which demand the employment of an empirical factor."

Phenolic insecticides and fungicides, G. P. Gray (California Sta. Bul. 269 (1916), pp. 327-381, figs. 9).—This bulletin is divided into three parts.

Part 1 gives a general discussion of phenolic insecticides and fungicides and a classification, description, and data as to the properties of materials found on the market, both of refined phenols and compounded remedies. It is indicated that all the cresols are more active fungicides than phenol. Commercial cresol is usually a mixture of the three cresols. The term crude cresylic acid is deemed more appropriate to be applied to the material commonly sold as crude carbolic acid.

Part 2 gives the classification and tabulation of the results of analyses of samples taken during the fiscal years 1911–12 and 1912–13, and comments. Aithough many products were found to be below guaranty, manufacturers and dealers are not accused of willfully making or selling low-grade or non-standard products. It appears, however, that material has often been guarantied and sold with but little knowledge of its composition.

Part 3 gives methods of examination and descriptions of apparatus, including a steam distillation battery, a mechanical shaker, and a small device for holding flasks in a water bath. Qualitative methods most frequently used are described and references to methods for the complete examination of the material used by the U. S. Department of Agriculture are included.

Progress in peanut milling, T. B. Reese (Texas Sta. Circ. 12, n. ser. (1916), pp. 3-6).—This circular describes in detail the methods commonly used in peanut milling. It is indicated that the cost of milling peanuts at the present time is greater than that of milling cotton seed. The cost of a ton of farmer's stock, which includes from 200 to 300 lbs. of waste, is about \$55. The products from this material, viz. about 65 gal. of oil and about 1,200 lbs. of cake, will yield the miller about \$64, or a margin of \$9.

Some chemical changes in the resweating of seed-leaf tobacco, H. R. Kray-Bill. (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 336-339).—The investigation is summarized as follows:

"The greatest loss of dry matter during the resweating process occurs in the proteins, nicotin, ether extract, and nitrogen-free extract. The total nitrogen, ammonia, nitric acid, and crude fiber show slight losses. The amids and reducing substances show an increase. The changes during the resweat are quite similar to those of the first sweating process. It seems, therefore, that the resweat is a continuation of the first sweating process. . . .

"The total loss in nitrogen is 0.61 per cent. The difference between the total loss of nitrogen and the loss of nitrogen as nitric acid, ammonia, and amids (loss of protein nitrogen minus amid gain in nitrogen) is 0.28 per cent. It appears from this that most of the nicotin which is lost is lost by volatilization. This is in accord with the results of Garner [E. S. R., 20, p. 936].

"It is evident that a breaking down of proteins into amids occurs. From this we can readily see that there is probably an enzym present which is capable of breaking down the proteins. Since the increase in amid nitrogen is not so great as the loss in protein nitrogen it suggests that there may be present a ferment which breaks up the amino acids, although no definite conclusions can be drawn."

METEOROLOGY-WATER.

Report of the meteorological station at Berkeley, California, for the year ending June 30, 1914, W. G. Reed (Univ. Cal. Pubs., Georgr., 1 (1916), No. 9, pp. 373-439, pls. 12, figs. 9).—The instrumental installation and the character and methods of observations made are briefly described, and observations on temperature, pressure, precipitation, atmospheric moisture, frost, and wind are reported. A summary of the results of a hydrographic survey (rainfall and run-off) of Strawberry Creek, near the university, is also included.

The mean annual temperature for the year was 58° F. The extreme range of temperature was about 70°. September was the warmest month and December the coldest. The maximum temperature, 105.5°, occurred September 16, 1913; the minimum, 36°, was recorded December 15, 1913, and January 9, 1914. Frost occurred from November to March. The relative humidity averaged 86 per cent morning and night, and the mean dew point was about 44° in winter and 54° in summer. Nearly 40 per cent of the days were generally clear. Fog was observed on 29 days. The total precipitation was 33.58 in. or 7.12 in. more than the average.

Meteorological observations, J. S. Stevens (Maine Sta. Bul. 245 (1915), pp. 309-310).—A monthly and annual summary of observations at the University of Maine on temperature, precipitation, cloudiness, and wind movement during 1915 is given. The mean temperature for the year was 46.21° F., as compared with an average of 42.73° for 47 years; the total precipitation was 38.87 in., as compared with mean annual precipitation of 42.67 in. for 47 years; the snowfall was 49.1 in., as compared with 87.34 in. as the average of 47 years; the number of clear days was 177; the number of cloudy days, 121; and the total movement of wind was 48,224 miles.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and D. POTTER (Massachusetts Sta. Met. Buls. 327, 328 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1916, are presented. The data are briefly discussed in general notes on the weather of each month.

Weather summaries, L. R. Waldron (North Dakota Sta., Rpts. Dickinson Substa., 1911, pp. 13, 14; 1912, pp. 16, 17; 1913, pp. 37-39).—Observations at Dickinson, N. Dak., during 1911, 1912, and 1913 on temperature and rainfall are summarized by months and compared with the normals. Data relating to early and late frosts are also given.

Climatic conditions of Minnesota, U. G. PURSSELL (*Univ. Minn., Geol. Survey Bul. 12* (1915), pp. 10–29, figs. 12).—The geographic and physiographic features which affect the climate of the State are briefly described.

The climate is continental, modified to a considerable extent by numerous inland bodies of water. The State "is in the path of a large proportion of the low-pressure areas which move across the United States from west to east. These areas move at an average speed of 600 miles in 24 hours and are preceded by southerly winds and higher temperature and followed by northerly winds and lower temperature. They are usually accompanied by cloudy weather and precipitation, each storm causing an average of from one to two rainy days as it crosses the State. As there is an average of almost two of these storms each

tartaric acid to a permanent slight acid reaction. Starch is now added, and the liquid titrated with tenth-normal iodin.

From the titration figures obtained from this procedure and those previously described the various forms of sulphur existing in the dilute lime-sulphur solution can be calculated by formulas which are submitted. Suggestions on the execution of the proposed method are discussed in detail.

It is concluded that "the use of a single standard solution which can be so easily and accurately prepared and used as tenth-normal iodin means a possibility of increased accuracy, as well as a saving of time, over the gravimetric estimation of sulphur as barium sulphate under conditions which demand the employment of an empirical factor."

Phenolic insecticides and fungicides, G. P. Gray (California Sta. Bul. 269 (1916), pp. 327-381, figs. 9).—This bulletin is divided into three parts.

Part 1 gives a general discussion of phenolic insecticides and fungicides and a classification, description, and data as to the properties of materials found on the market, both of refined phenols and compounded remedies. It is indicated that all the cresols are more active fungicides than phenol. Commercial cresol is usually a mixture of the three cresols. The term crude cresylic acid is deemed more appropriate to be applied to the material commonly sold as crude carbolic acid.

Part 2 gives the classification and tabulation of the results of analyses of samples taken during the fiscal years 1911–12 and 1912–13, and comments. Although many products were found to be below guaranty, manufacturers and dealers are not accused of willfully making or selling low-grade or non-standard products. It appears, however, that material has often been guarantied and sold with but little knowledge of its composition.

Part 3 gives methods of examination and descriptions of apparatus, including a steam distillation battery, a mechanical shaker, and a small device for holding flasks in a water bath. Qualitative methods most frequently used are described and references to methods for the complete examination of the material used by the U. S. Department of Agriculture are included.

Progress in peanut milling, T. B. Reese (Texas Sta. Circ. 12, n. scr. (1916), pp. 3-6).—This circular describes in detail the methods commonly used in peanut milling. It is indicated that the cost of milling peanuts at the present time is greater than that of milling cotton seed. The cost of a ton of farmer's stock, which includes from 200 to 300 lbs. of waste, is about \$55. The products from this material, viz, about 65 gal. of oil and about 1,200 lbs. of cake, will yield the miller about \$64, or a margin of \$9.

Some chemical changes in the resweating of seed-leaf tobacco, H. R. Kraybell (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 336-339).—The investigation is summarized as follows:

"The greatest loss of dry matter during the resweating process occurs in the proteins, nicotin, ether extract, and nitrogen-free extract. The total nitrogen, ammonia, nitric acid, and crude fiber show slight losses. The amids and reducing substances show an increase. The changes during the resweat are quite similar to those of the first sweating process. It seems, therefore, that the resweat is a continuation of the first sweating process. . . .

"The total loss in nitrogen is 0.61 per cent. The difference between the total loss of nitrogen and the loss of nitrogen as nitric acid, ammonia, and amids (loss of protein nitrogen minus amid gain in nitrogen) is 0.28 per cent. It appears from this that most of the nicotin which is lost is lost by volatilization. This is in accord with the results of Garner [E. S. R., 20, p. 936].

"It is evident that a breaking down of proteins into amids occurs. From this we can readily see that there is probably an enzym present which is capable of breaking down the proteins. Since the increase in amid nitrogen is not so great as the loss in protein nitrogen it suggests that there may be present a ferment which breaks up the amino acids, although no definite conclusions can be drawn."

METEOROLOGY-WATER.

Report of the meteorological station at Berkeley, California, for the year ending June 30, 1914, W. G. Reed (Univ. Cal. Pubs., Georgr., 1 (1916), No. 9, pp. 373-439, pls. 12, figs. 9).—The instrumental installation and the character and methods of observations made are briefly described, and observations on temperature, pressure, precipitation, atmospheric moisture, frost, and wind are reported. A summary of the results of a hydrographic survey (rainfall and run-off) of Strawberry Creek, near the university, is also included.

The mean annual temperature for the year was 58° F. The extreme range of temperature was about 70°. September was the warmest month and December the coldest. The maximum temperature, 105.5°, occurred September 16, 1913; the minimum, 36°, was recorded December 15, 1913, and January 9, 1914. Frost occurred from November to March. The relative humidity averaged 86 per cent morning and night, and the mean dew point was about 44° in winter and 54° in summer. Nearly 40 per cent of the days were generally clear. Fog was observed on 29 days. The total precipitation was 33.58 in. or 7.12 in, more than the average.

Meteorological observations, J. S. Stevens (Maine Sta. Bul. 245 (1915), pp. 309-310).—A monthly and annual summary of observations at the University of Maine on temperature, precipitation, cloudiness, and wind movement during 1915 is given. The mean temperature for the year was 46.21° F., as compared with an average of 42.73° for 47 years; the total precipitation was 38.87 in., as compared with mean annual precipitation of 42.67 in. for 47 years; the snowfall was 49.1 in., as compared with 87.34 in. as the average of 47 years; the number of clear days was 177; the number of cloudy days, 121; and the total movement of wind was 48,224 miles.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and D. Potter (Massachusetts Sta. Met. Buls. 327, 328 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1916, are presented. The data are briefly discussed in general notes on the weather of each month.

Weather summaries, L. R. Waldron (North Dakota Sta., Rpts. Dickinson Substa., 1911, pp. 13, 14; 1912, pp. 16, 17; 1913, pp. 37-39).—Observations at Dickinson, N. Dak., during 1911, 1912, and 1913 on temperature and rainfall are summarized by months and compared with the normals. Data relating to early and late frosts are also given.

Climatic conditions of Minnesota, U. G. PURSSELL (*Univ. Minn., Geol. Survey Bul. 12* (1915), pp. 10-29, figs. 12).—The geographic and physiographic features which affect the climate of the State are briefly described.

The climate is continental, modified to a considerable extent by numerous inland bodies of water. The State "is in the path of a large proportion of the low-pressure areas which move across the United States from west to east. These areas move at an average speed of 600 miles in 24 hours and are preceded by southerly winds and higher temperature and followed by northerly winds and lower temperature. They are usually accompanied by cloudy weather and precipitation, each storm causing an average of from one to two rainy days as it crosses the State. As there is an average of almost two of these storms each

Effect of grinding on the lime requirement of soils, R. C. Cook (Soil Sci., 1 (1916), No. 1, pp. 95-98).—Experiments conducted at Rutgers College on six different soils are reported, the results of which are taken to indicate that "soils should not be ground if used for determination of lime requirement by the Veitch method. Grinding sandy soils of New Jersey increases their acidity instead of decreasing it, according to the method employed."

Albuminous bases formed from organic matter of soils by hydrolysis, A. Shmuk (Zhur. Opytn. Agron., 16 (1915), No. 4, pp. 281–298; abs. in Chem. Abs., 10 (1916), No. 2, p. 243).—By long enough boiling of soil or humic acid with 25 per cent sulphuric acid the author succeeded in isolating and identifying two compounds which he classed as amino acids. Arginin and lysin were found in compounds obtained from three different chernozem soils.

[Soil moisture studies] (North Dakota Sta., Rpt. Dickinson Substa., 1913, pp. 31-36, figs. 4).—Studies on four loam soil wheat plats (A) continuously cropped, spring plowed, (B) continuously cropped, fall plowed, and (C and D) alternately cropped and summer fallowed showed an increase in moisture in all the plats between October and April and a decrease during the remainder of the season. The spring-plowed plat showed considerably less moisture than the fall-plowed plat. Plats C and D showed about the same amounts of water available to the crop until the crop began to draw heavily on the available water, after which the plat recently fallowed lost but little water, while the upper 3 ft. of the other plat became as dry as plats continuously cropped. In the lower 3 ft. of the fall-plowed plat and Plats C and D there was an increase in the amount of growth water from the fall until the following spring. In the spring-plowed plat there was a decrease. The water available to crops was used most economically on the spring-plowed plats.

Similar data for barley plats are also reported, but are apparently deemed unsatisfactory.

Soil gases, J. W. Leather (Mem. Dept. Agr. India, Chem. Ser., 4 (1915), No. 3, pp. 81–134, figs. 4).—An apparatus for the abstraction of soil gases from undisturbed soil samples and a method of estimation of the argon content of the soil are described, and results of studies of Pusa and other Indian soils are reported. The object was to obtain more definite information regarding the gases present during the decomposition of green manure, the gases of swamp rice soil, the assimilation of nitrogen by Papilionaceæ, the gases present near the roots of crops, and changes during nitrification.

It was found that the volume of gas in soils determined by direct measurement is approximately equal to that determined by indirect calculation. The volume of condensed gas in Pusa soil was too small to be estimated accurately and is thought to be not greater than 4 per cent of the gas present. The volumes of gas were smaller in wet weather than when the soil was dry. "The volume of displaced gas is not necessarily equal to the additional water, and the experimental results also show that one volume of water does not necessarily displace one volume of gas. At the same time the two approach equality.

"The whole of the gas is not displaced from a soil; even during the wettest weather the proportionate volume of gas only falls to 15 or 20 per cent, or about one-half the volume which is present during long periods of hot, dry weather.

"The soil gas of land which has been freshly treated with farm manure or green manure naturally contains a high proportion of carbon dioxid and a low proportion of oxygen, but it is evident from the information gained by operating with closed vessels (containing abundance of air) that were it not

for the process of diffusion, the proportions would be very different from what they are."

High proportions of carbon dioxid and frequently low proportions of oxygen were found in the neighborhood of the roots of such crops as hemp, indigo, and maize, together with small but definite quantities of hydrogen. "Although high proportions of carbon dioxid are frequently present in the gas as extracted from the soil, calculation shows that considerably the greater part is present in the dissolved state in the soil solution."

Determination of the ratios of oxygen and nitrogen to argon in the soil gases showed "that the chief changes in the soil have to do with the oxygen, whilst nitrogen-assimilation or nitrogen-evolution in dry land is at least so limited that it is usually difficult to detect. . . In cases like the gas from rice land, the argon determination demonstrates with certainty that most of the nitrogen is derived from the soil and manure. . . .

"It is certain that diffusion of gases through soils at a depth of from 12 to 15 in. is so efficient as to warrant the conclusion that cultivation of the surface soil is unnecessary for purposes of aeration. The well-established value of good cultivation must be referred to other causes."

Agronomic and soil conditions in the Selby smoke zone, C. F. Shaw and E. E. Free (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 451-462).—An investigation of the agronomic and soil conditions of the Selby smoke zone in Solano County, Cal., to determine the extent to which the vegetation is injured and the soil polluted by smelter fumes and dust in that district, is reported.

The opinion is expressed that while crop yields in the region are below what would be expected for such a climate, they may be attributed more to poor soil and poor agricultural practice than to some definite unfavorable factor such as smelter dust and fumes. With reference to soil pollution, it is concluded that "arsenic is certainly a normal, though extremely minute, constituent of the soils of the region, and lead is probably so. The past contamination of the soils by lead and arsenic from the smelter is possible but unproved and appears not to be susceptible of proof. The quantities of lead and arsenic added, if any, have been small and of the same order as the quantities of these elements normally present in the soils. The maximum amounts of lead and arsenic found are far too small to have any injurious effect on plants grown in the soils. Much larger amounts than those actually found would be without practical effect on the agriculture of the region."

Data regarding soil samples are included.

Mississippi: Its geology, geography, soils, and mineral resources, E. N. Lowe (Miss. Geol. Survey Bul. 12 (1915), pp. 335, pl. 1, figs. 28).—This is a popular report covering the geology, geography, mineral resources, underground waters, and soils of the State of Mississippi. The section on soils has been taken mainly from a previous report (E. S. R., 26, p. 811).

Soil survey of Johnson County, Missouri, B. W. Tillman and C. E. Deardorff (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 33, fg. 1, map 1).—This survey, made in cooperation with the Missouri Experiment Station and issued May 5, 1916, deals with the soils of an area of 531,840 acres in western Missouri, lying in the residual prairie section of the Great Plains region. The topography is rather more rolling than undulating and level. The county is well drained. The soils are classed as upland soils of residual origin, which cover about 85 per cent of the area, and lowland soils of alluvial origin. Sixteen soil types of 10 series are mapped, of which the

Summit, Boone, Osage, and Bates silt loams cover, respectively, 27.5, 26.9, 12.2, and 11.1 per cent of the area.

The soils of Antigua, H. A. Tempany (West Indian Bul., 15 (1915), No. 2, pp. 69-102, pls. 8).—This report deals primarily with the physical and chemical characteristics of the soils of an island area of 108 square miles, which topographically is divided into three principal regions: (1) A generally flat central plain, which traverses the island diagonally from west to east; (2) a northeastern limestone area consisting of undulating country; and (3) a mountainous southwestern area of volcanic origin.

The soils of the limestone area approximate very closely to a single physical type in which the particles of the fine silt and clay on the average constitute 65.9 per cent of the soil. "The soils of the low-lying central portion of the island... comprise a series of heavy clay soils deficient in calcium carbonate, requiring thorough tillage and drainage for the maintenance of tilth." The soils of the southern district are noncalcareous and well drained, and "approximate fairly closely to one physical type in which the larger and the smaller particles are nearly balanced."

Tables showing the mean physical composition of the principal soil types encountered on the island are appended.

Studies on soil protozoa, S. A. Waksman (Soil Sci., 1 (1916), No. 2, pp. 135-152).—Studies with loam soils of high and low humus content and clay soils on (1) the activity of protozoa in the soil, (2) the numbers and types of protozoa in different soils at different depths, and (3) the effect of protozoa on bacterial numbers and their decomposition of organic matter in the soil are reported.

It was found that moisture, humus content, and the structure of the soil were the important factors governing the activities of the protozoa. Sterilization of soil and the addition of easily soluble organic matter made the conditions optimum for protozoan activities at a lower moisture content than the corresponding unsterilized or untreated soils. The flagellates were the most common soil protozoa found active in the soil with moisture content too low for the development of the other groups.

"The flagellates are the largest group of soil protozoa; the greatest number of flagellates are found in the soil just below the surface; the ciliates at a depth of 4 in.; the numbers decrease with the depth, so that below 12 in. the soil is practically free from protozoa. Soil protozoa do not have any appreciable influence upon the ammonification by bacteria. The presence of protozoa acts detrimentally upon bacterial numbers, so that when the conditions become favorable for protozoa development, the bacterial numbers decrease."

The spirit of the soil, G. D. Knox (London: Constable & Co., Ltd., 1915, pp. XIII+242, pls. 16).—This book gives a popular account of nitrogen fixation in the soil by bacteria and of the production of auximones in bacterized peat according to Bottomley. It contains chapters on the nitrate problem; England's food supply in peace and war; bacteria and protozoa; peat and its uses; fixation of nitrogen by leguminous plants; humus; bacterized peat, its preparation and general properties; vitamins, accessory food bodies, and auximones; elementary conceptions of chemistry in relation to the soil; the testing of humogen; the preparation of humogen; and how humogen is applied. Two final sections give the results of experience along the above lines.

It is the main contention of this book "that soil inoculation scientifically carried out will greatly increase the yield of the land that is already under cultivation, and that it will bring into cultivation large tracts of land that it has hitherto not paid to cultivate, and that by the stimulation of plants it will

be possible to bring fruit and flowers to maturity earlier than can be done by other means"

Considerable space is devoted to the newly discovered accessory food bodies or auximones in bacterized peat. A number of different experiments are reported, the results of which are taken to indicate "conclusively that bacterized peat contains a substance or substances which stimulate the growth of the plant and enable it to utilize the normal food constituents supplied to it. In nature the need is doubtless supplied by the decaying organic matter in the soil."

Bacterial activities and crop production, P. E. Brown (*Iowa Sta. Research Bul. 25* (1915), pp. 359-388).—The substance of this bulletin has been previously noted from another source (E. S. R., 34, p. 619).

The reclamation of bog land (Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 2. pp. 229-236, pls. 10).—A number of pot and field experiments conducted for three years with different common crops on Irish bogs are reported, the results of which are taken to indicate that lime is the limiting factor in the reclamation of Irish bogs while phosphate is next in importance.

"Notwithstanding the large amount of nitrogen in the peat, the necessity of supplying this ingredient in a form in which the plant can use it was clearly demonstrated. . . . As long as the different crops were producing leaf and stem only, potash was the least important of the four ingredients, but its influence was most marked in filling the grain and stiffening the straw in the case of the rye and of increasing the yield of tubers in the case of the potato."

An experiment with marls and shell sands as substitutes for lime on these soils showed that most of the marls and shells tested were as good as burned lime.

Analysis of plants and soils to determine the amounts of nutritive substances in soils, T. Pfeiffer, E. Blanck, W. Simmermacher, and W. Rathmann (Landw. Vers. Stat., 86 (1915), No. 5-6, pp. 339-391; abs. in Chem. Zentbl., 1915, II, No. 5, pp. 239, 240; Ztschr. Angew. Chem., 28 (1915), No. 65, Referatenteil, p. 421; Jour. Chem. Soc. [London], 108 (1915), No. 634, I, pp. 763, 764; Jour. Soc. Chem. Indus., 34 (1915), No. 18, p. 972).—Pot and laboratory experiments with seven different soils to determine the usefulness of plant and soil analysis in estimating the fertilizer needs of soils are reported, being based in part on the results of previous work (E. S. R., 29, p. 514).

The conclusion is drawn that in establishing uniformity in the available water content of different soils, the content of hygroscopic water represents the water content at which plant growth starts only in so far as with increasing hygroscopicity of the soils a corresponding water addition is necessary. On this basis, crop substances were obtained on different soils which showed only a slight variation in the content of the nutritive constituent present in minimum, or the so-called normal content. This is taken to indicate that the physical properties of soil are not of great importance in plant production in so far as they do not influence the factor water. It is concluded further that the so-called normal content of any nutritive constituent does not offer a sufficient comparative basis on which to interpret plant analysis in terms of fertilizer needs of the soil.

It was further found that the amount of nitrogen taken up by plants from an unmanured soil was only slightly increased by manuring with an excess of phosphoric acid and potassium. Assimilation of phosphoric acid, on the other hand, was much more influenced by application of nitrogen and potassium, partly owing to greater root development and partly to increased solubility of the soil phosphates, which varied with different soils. The same held good in the case of potassium.

Oat plants assimilated only about 10 per cent of the phosphoric acid dissolved by 1 per cent hydrochloric acid, while with potassium the results agreed much more closely. Water saturated with carbon dioxid dissolved much less phosphoric acid than was assimilated by oats in the same soil. In this case the difference is attributed to the presence of organic acids in the roots, to the dissolving action of manurial salts, and to disturbances in the equilibrium of the soil solution. It is thought that the potassium fixed by absorption in soils, as estimated by Kellner, can not be the only source of potassium available to plants. While it was found that neither analysis of plants nor soil analysis, as employed, is suitable for establishing the amounts of nutrients in soils, it is considered likely that useful indications will be obtained by ascertaining the maximum amounts of nutritive substance which give increased yields.

Carbon and nitrogen changes in the soil variously treated: Soil treated with lime, ammonium sulphate, and sodium nitrate, R. S. Potter and R. S. Snyder (Soil Sci., 1 (1916), No. 1, pp. 76-94, pl. 1, figs. 2).—The work of others bearing on the subject is briefly reviewed, and pot experiments conducted at the Iowa Experiment Station to determine the influence of additions per acre of 3 tons of calcium carbonate, 1,285 lbs. of sodium nitrate, 1,000 lbs. of ammonium sulphate, and of combinations of calcium carbonate with each of the nitrogen fertilizers in the amounts noted, on nitrogen losses, carbon dioxid evolution, and on changes in the ammonia, nitrate, nitrogen, and carbonate contents of an acid silt loam soil low in organic matter, are reported.

It was found that "for all the soils except those treated with both ammonium sulphate and lime, about 0.3 lb. of ammonia nitrogen was given off in 12 weeks. If kept up throughout the year, this would mean a loss of a little over a pound per acre in a year, an insignificant amount when compared to that lost by leaching, cropping, etc. The loss from the soils treated with both lime and ammonium sulphate was about ten times as high for the period of the experiment, but it is not at all probable that this rate would be held for a very long period after the application of the sulphate. Therefore, . . . the danger of loss of ammoniacal nitrogen from the soil of the type used is practically negligible. In a general way, the total nitrogen determinations show there is a smaller loss or a greater gain of nitrogen for the limed soils than the corresponding unlimed soils."

The results with reference to the amounts of carbon dioxid evolution were inconclusive and the experiment is being continued.

A list of 22 references to literature bearing on the subject is given.

The influence of some common humus-forming materials of narrow and of wide nitrogen-carbon ratio on bacterial activities, P. E. Brown and F. E. Allison (Soil Sci., 1 (1916), No. 1, pp. 49-75).—Experiments, conducted at the Iowa Experiment Station, with a slightly acid sandy loam soil low in organic matter content to determine the influence of applications per acre of 15 tons of each of horse, cow, and rotted manure; 2.5 tons of oat straw; 3 tons of corn stover; 2 tons of timothy hay; and 4 tons of each of cowpea and clover hay, on ammonification, nitrification, and nitrogen fixation, are reported.

It was found that "application of the common humus-forming materials in maximum amounts for farm conditions and in a dried condition increased bacterial activities, ammonification, nitrification, and azofication to a considerable extent. Horse manure, cow manure, and rotted manure gave the greatest effect on ammonification in most cases, although timothy hay surpassed the horse manure and cow manure in the extent of its effect in several instances. The oat straw and corn stover had a lesser effect than the manures, and the legume hays, clover, and cowpeas showed the least effect on ammonification of any of the materials used.

"Increases in ammonification due to the applications of humus-forming materials were independent of the nitrogen-carbon ratio of the materials added.... The dried-blood-fresh-soil method gave better results for ammonification than the casein-fresh-soil method. The latter gave better duplicate results, but the differences between different soils were not nearly so pronounced....

"Nitrification was increased in much the same way as ammonification by the various organic materials. The leguminous green manures exerted, however, somewhat greater effects than the manures, and also more influence than the nonlegumes. These results were the opposite of those secured with ammonification, but the differences were not great enough to permit of definite conclusions. Increases in nitrification brought about by the various materials were apparently independent of the nitrogen-carbon ratio in the substances. Indications of a greater effect of materials of a narrower ratio over those of a wide ratio can not be considered conclusive.

"Azofication or nonsymbiotic nitrogen fixation was favored by manure to a large extent. Straw, stover, and nonleguminous hays had almost as great an effect as to the manures, and the leguminous hays had the least effect of any of the materials used. The nitrogen-carbon ratios of the materials employed were of little or no significance in indicating their effects on azofication. There were indications, however, that nonlegumes and straws might increase azofication in soils to a large enough extent to make their use more profitable than that of legumes. . . . Dextrose gave better results in the azofication experiments than mannite. . . .

"There was little similarity between the effects of the different organic materials on the different bacterial processes. . . . The manures and legumes increased the first crop of oats, except in the case of the horse manure, which apparently exerted an injurious effect on the crop in its early stages of growth. . . .

"The substances with wide nitrogen-carbon ratio decreased the crop yield, while those of narrow ratios gave increases. The nitrogen factor was evidently very important on this soil. The nitrogen-carbon ratio of the organic materials seemed to be of importance in determining the influence on the first crop of oats. If opportunity is to be given for nonlegumes to exert as good an effect as legumes, by increasing azofication to a sufficient extent to offset the nitrogen supplied by the legumes, the organic materials must be allowed sufficient time for considerable decomposition to occur before a crop is grown... The influence of the various substances applied to the soils was noted on a second crop of oats, but the relative effects were different. The nonlegumes had as great an influence as the legumes... The nitrogen-carbon ratio of the materials applied to the soil did not seem to be of as much importance in determining the effect on the second crop of oats as in the case of the first crop."

Four references to literature bearing on the subject are cited.

Contribution to the question of the action of stimulants on plant development, B. Schulze (Landw. Vers. Stat., 87 (1915), No. 1, pp. 1–24, fig. 1; abs. in Jour. Chem. Soc. [London], 108 (1915), No. 636, I, p. 926; Jour. Soc. Chem. Indus., 34 (1915), No. 22, p. 1157; Chem. Zentbl., 1915, II, No. 11, p. 622).—Pot experiments on a clay soil mixed with compost to determine the stimulating influence of the hydroxid, carbonate, nitrate, phosphate, and sulphate of manganese and of aluminum sulphate, singly and in different combinations, on the growth of sugar beets, when added in amounts equivalent to from 1.2 to 12.2 gm. of manganese per 20 kg. of soil, are reported.

It was found that all the manganese salts used produced an increase in the beet root yield. The most favorable influence was exerted by the manganese phosphate in all amounts added and by the combination of manganese sulphate with aluminum sulphate. The small additions of manganese nitrate produced the greatest increases. All increases in yield are attributed only to the stimulating influence of the manganese.

A second set of pot experiments on a productive cultivated soil to determine the influence of a radio-active fertilizer on the growth of oats, white mustard, and peas when added in amounts of 0.4, 0.8, 1.6, and 4 gm. per 21 kg. of soil in zinc pots, and in amounts of 0.23, 0.46, 0.92, and 2.3 gm. per 13 kg. of soil in clay pots, is reported. It was found that the radio-active fertilizer was especially active in stimulating fruit formation and that this influence was exerted without an undue exhaustion of the nutritive constituents in the soil. No injury to the crops through the larger additions of the radio-active fertilizer was observed.

The influence of certain organic materials upon the transformation of soil nitrogen, R. C. WRIGHT (Jour. Amer. Soc. Agron., 7 (1915), No. 5, pp. 193-208, figs. 7).—Experiments on the influence of dried, fresh, and rotted stable manure, mature wheat straw, starch, cellulose, glucose, dextrose, and green manures on nitrogen in the forms of ammonium sulphate, potassium nitrate, and peptone and on the original nitrogen in sandy and clay loam soils, greenhouse bench soil, orange grove soil, and silty loam soil are reported.

From the results the conclusion is drawn "that in agricultural practice the plowing under, in an undecayed state, of straw or strawy material such as old hay, litter, leaves, stalks, strawy manure, fresh stable manure, and even green manures or cover crops that have been allowed to become mature or nearly so, will serve to reduce the quantity of available nitrogen in a soil. When such a practice is followed only during fall plowing and in a region with a fairly open winter . . . a sufficiently advanced stage of decomposition would be reached by spring not to interfere with normal nitrification. . . . Plowing under of green manures presents a different problem because very little resistant cellulose material is added. Such succulent green material is readily attacked by saprophytic micro-organisms and rather rapid decay accompanied by vigorous nitrification takes place, thus maintaining the supply of available nitrogen."

The fixation of nitrogen in stable manure, Gerlach (Ztschr. Ver. Deut. Zuckerindus., No. 717 (1915), II, pp. 547-554, fig. 1).—The results of several experiments are briefly reported which indicate that the addition of superphosphate, certain potash salts such as kieserit, or acid salt by-products from chemical industries to liquid manure in amounts sufficient to produce an acid reaction will cause a marked reduction in nitrogen losses. A film of oil over the top of liquid manure had the same effect. Everything considered, however, the best results were obtained from the use of superphosphate.

Fertilizer experiments with different ammonium salts in Weihenstephan in 1915, Ahr (Mitt. Deut. Landw. Gesell., 30 (1915), No. 46, pp. 696-699).— Field experiments with early potatoes and with rotations of wheat, oats, and potatoes and potatoes, wheat, and beets on marly loam and deep mild loam soils to compare the fertilizing value of ammonium chlorid, ammonium carbonate, ammonium-sodium sulphate, ammonium nitrate, ammonium sulphate, sodium nitrate, calcium nitrate, and lime nitrogen with nitrogen contents of 23.1, 16.76, 7.65, 34.2, 19.9, 16.01, 12.64, and 19 per cent, respectively, are reported. The fertilizers were added in amounts equivalent to 30, 45, and 60 kg. per hectare (26.7, 40, and 53.4 lbs. per acre) of nitrogen.

It was found that the ammonium salts, the ammonium-sodium sulphate and ammonium chlorid gave results equal to those given by ammonium sulphate. Ammonium carbonate was too unstable to be effectively handled. Lime nitrogen when properly used gave results very little inferior to those given by the other fertilizers. Ammonium nitrate was found to be an effective and easily handled fertilizer. All the fertilizers gave increases in spite of the already rather high producing power of the soil for beets, calcium nitrate being in general more effective for this crop than sodium nitrate or ammonium nitrate.

Fixation of atmospheric nitrogen, L. L. Summers (Trans. Amer. Electrochem. Soc., 27 (1915), pp. 339-383, figs. 5).—This article reviews the known processes of commercial nitrogen fixation, points out that the electrical processes for nitrogen fixation have a very low efficiency, and maintains that combinations of electrical and chemical methods promise the most important developments. Comparative figures are given showing the amount of energy necessary per kilogram of nitrogen fixed, and the general economics of the subject are discussed.

The cyanamid process, F. S. Washburn (*Trans. Amer. Electrochem. Soc.*, 27 (1915), pp. 385-407).—The details and economics of this and related processes are discussed.

The utilization of bones as fertilizer, F. LAVENIR (Bol. Min. Agr. [Buenos Aires], 19 (1915), No. 8-9, pp. 569-576).—The results of analyses of fresh, degreased, and burned bones are reported and discussed, and methods of treatment described. It is considered evident that for certain plants (especially alfalfa) the treatment of bones by heat or with sulphuric acid to form superphosphate is not justified.

A reconnoissance for phosphate in the Salt River Range, Wyoming, G. R. MANSFIELD (U. S. Geol. Survey Bul. 620-O (1916), pp. 331-349, pl. 1).—This report describes the geography and geology of the locality and reports a study of the phosphate deposits.

"The data thus far available indicate that the phosphate deposits of the Salt River Range are probably inferior to those of southeastern Idaho both in thickness and in quality. There is, however, a considerable body of medium-grade rock which may be considered as a valuable reserve deposit. If the plan of grinding and applying phosphate rock directly to the soil without chemical treatment is found to produce beneficial results, some local demand for this rock might be developed."

The effect of superphosphate on the wheat yield in New South Wales, W. L. Waterhouse (Dept. Agr. N. S. Wales, Sci. Bul. 10 (1913), pp. 10).—An examination of the soils of the northern, western, and southern sections of New South Wales led to the conclusion that there is a relation between the responsiveness of these soils to the application of superphosphate in the production of wheat and the phosphoric acid content of the soils. This relation is more marked for the available phosphoric acid than for the total phosphoric acid content.

Evaporation of brine from Searles Lake, California, W. B. Hicks (U. S. Geol. Survey, Prof. Paper 98-A (1916), pp. 1-8, figs. 2).—In continuation of experiments previously noted (E. S. R., 34, p. 425) samples of natural brine from Searles Lake, Cal. (E. S. R., 33, p. 518), were subjected to fractional evaporation and crystallization. "The data recorded indicates that carefully controlled fractional evaporation and crystallization, possibly combined with other treatment, promise much as a means of obtaining potassium from brines similar to that of Searles Lake."

Twenty questions on lime, F. E. Bear (West Virginia Col. Agr. Ext. Dept. Circ. 47 (1915), pp. 16, figs. 7).—This is a brief popular summary of results obtained at different state experiment stations on the purchase, preparation, and use of different forms of lime in agriculture.

Sulphur in relation to soils and crops, J. W. Ames and G. E. Boltz (Ohio Sta. Bul. 292 (1916), pp. 221-256).—This bulletin deals with the sulphur supply of soils, reporting analyses of typical Ohio soils, and reports field experiments at the different experimental farms of the Ohio Station to determine the importance of sulphur as a factor in crop production.

It was found that "soils well supplied with organic matter contain more sulphur than soils containing a smaller amount of organic residues. Sulphur is similar to phosphorus in that larger amounts of both these elements are distributed in the surface soil than in the lower strata.

"Treatment with fertilizer materials supplying sulphates increased the sulphur content of the soil over that found in unfertilized soil. Soil treated with acid phosphate and ammonium sulphate contained more sulphur than soil receiving acid phosphate alone. Cultivation of silt loam soil for 16 years without the addition of fertilizers decreased the total sulphur supply.

"Water extract of soils obtained by leaching 200 gm. of soil with 2,000 cc. of water shows that there is a considerable accumulation of sulphates in silt loam soil deficient in organic matter. Treatment with acid phosphate has not increased the sulphate content over that found in unfertilized soil. Ammonium sulphate used in combination with acid phosphate decidedly increased the accumulation of sulphates. . . . A much less proportion of the total sulphur is found in the water extract of soils containing more organic matter and total sulphur. The amount of soluble sulphur obtained in the water extract of soils indicates a sufficient supply of available sulphur, assuming that sulphur as sulphates is a satisfactory form of this element.

"The 20-year average yields of the Wooster 5-year rotation fertility experiments show that phosphorus carriers (acid phosphate and dissolved bone black) containing sulphates, compared with bone meal and basic slag, produced more corn, oats, and wheat. Bone meal and basic slag increased the yields of clover and timothy....

"Acid phosphate, compared with bone meal and basic slag in a 3-year rotation of potatoes, wheat, and clover has given larger yields of potatoes and wheat. In the 5-year rotation experiment conducted for 19 years on Strongsville clay, containing more sulphur than the Wooster silt loam, acid phosphate, compared with bone meal and basic slag, has given larger yields of corn, oats, and timothy. The yields obtained show that bone meal and basic slag are more effective than the dissolved boneblack used on this soil. The 3-year rotation fertility plats on Miami clay loam, which have had sulphur supplied by both acid phosphate and potassium sulphate, have produced less tobacco, wheat, and clover than plats to which muriate of potash and acid phosphate were added. . . .

"Under certain conditions of treatment, sulphates have increased the yield of soy-bean hay and the sulphur content of the crop. The addition of calcium sulphate to fertilizer treatment furnishing nitrogen, phosphorus, and potassium decreased the sulphur content of soy beans. Potassium sulphate and ammonium sulphate, compared with potassium chlorid and sodium nitrate, gave an increased yield of beans having a lower percentage of sulphur. Sulphates used with complete fertilizer and calcium carbonate decreased the yields of millet hay and millet seed. Sulphates considerably increased the accumulation of sulphur in millet hay and in soy-bean hay and decreased the content in the seed. No inorganic sulphur was found in soy beans and millet seed. Calcium sulphate in

221

addition to complete fertilizer increased the yield of rape. The proteid nitrogen and organic sulphur content of rape grown on soil treated with sulphates in addition to dicalcium phosphate, potassium chlorid, and sodium nitrate has been increased. The increased amount of sulphur assimilated by the rape crop, from soil treated with sulphur in addition to phosphorus, potassium, and nitrogen, is mostly combined as organic sulphur. The nonproteid nitrogen found in the rape plant grown under the conditions of this experiment is in excess of the proteid nitrogen.

"On limed soil calcium and magnesium sulphate, in addition to phosphorus, potassium, and nitrogen, increased the yield over that from similarly treated plats receiving no sulphates. Potassium and ammonium sulphate on limed soil also produced more rape than plats where potassium chlorid and sodium nitrate furnished the potassium and nitrogen. Magnesium sulphate, where used with complete fertilizer and calcium carbonate, produced more soy beans and millet seed than calcium sulphate.

"The use of sulphur and hydrogen sulphid in pot tests increased the acidity of the soil. Pots so treated gave a greater weight of clover than the untreated or limed pots.

"Experimental data obtained by extracting mixtures of soil, sulphur, and rock phosphate with 0.2 per cent hydrochloric acid indicate that oxidation of sulphur has increased the solubility of the insoluble phosphorus."

A list of 25 references to literature bearing on the subject is appended.

The fertilizing power and harmfulness of fertilizing materials, A. VIVIEN (Bul. Assoc. Chim. Sucr. et Distill., 32 (1914), No. 1-2, pp. 36-42; abs. in Chem. Abs., 9 (1915), No. 21, p. 2962).—The author reviews work by himself and others showing the toxic effect of different salts on plants, and gives the toxic dose of each of 16 sodium, potassium, ammonium, and calcium salts for Bordeaux wheat. It is pointed out that sugar beets may be grown on soils containing amounts of salts which would be toxic to other crops, as the beets absorb the salts and gradually remove the excess of mineral matter from the soil. Such beets are said, however, to yield a sugar solution of low purity.

Fertilizer registrations for 1916, C. S. CATHCART (New Jersey Stas. Bul. 290 (1916), pp. 3-32).—This bulletin contains a list of 1,137 brands of fertilizers and their guaranties, as registered in New Jersey for the year ending October 31. 1916.

AGRICULTURAL BOTANY.

An experimental study of the rest period in plants: Physiological changes accompanying breaking of the rest period, W. L. Howard (*Missouri Sta. Research Bul. 21, pp. 3-72, figs. 10*).—In continuation of the author's study on the rest period of plants (E. S. R., 33, p. 520), a description is given of physiological investigations conducted to secure information on the specific effects produced by anesthetics and other agents employed in breaking the rest period of woody plants.

As a result of respiration and other studies, the conclusion is believed justified that the specific effect of all rest period breaking agents on dormant woody tissue is the stimulation of the enzyms. The rest period is believed to begin with the inhibition of enzyms by the accumulation of the products of their work. This may take place in mid or late summer. In the fall an excess supply of carbohydrates continues to be accumulated with the further inhibition of enzyms. This brings about the main or middle state of rest. Toward the end of this period enzyms become more and more active, giving place to the beginning of growth. The length of the rest period is said to vary greatly

with the different species, in some extending from June or July to March or April, while with others growth may begin again after two or three weeks of dormancy.

An extensive bibliography is appended.

The bearing of certain senile changes in plants on present theories of senility, H. M. Benedict (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 286).—
In a previous publication (E. S. R., 34, p. 222), the author described senile degeneration in Vitis vulpina, and in the present paper he gives an account of various theories regarding this phenomenon. He favors that advanced by Kassowitz, that senility is due to an accumulation of inert catabolic products, and he suggests that a more fundamental cause of senility may be found in the colloidal constitution of protoplasm with its units in the form of molecular complexes.

The favorable influence of nitrogen salts on seeds sensitive to light, G. GASSNER (Jahrb. Wiss. Bot. [Pringsheim], 55 (1915), No. 2, pp. 259-342; abs. in Ztschr. Bot., 7 (1915), No. 9, p. 580).—Giving the detailed results of extensive experimentation, the author states that the germination of seeds of Ranunculus sceleratus, Enothera biennis, and Chloris ciliata is favorably influenced by light. This effect in case of the first named required variations of temperature, and these variations themselves favored germination. In case of E. biennis, light favored germination at both constant and varying temperatures. Seeds of C. ciliata, when freed from chaff, were not so influenced by temperature variations, and light acted favorably in this respect only at temperatures of about 20° C. and upward. It is stated that germination is favored not by nutritive media as such, but by salts containing nitrogen as nitrites, nitrates, and ammoniates, the effects of which in this respect are perceptible through a very wide range of concentrations.

The author also discusses recent related experimentation as reported by Ottenwälder (E. S. R., 33, p. 826).

New instances of the promotion of germination, by nitrogen compounds, of seeds sensitive to light, G. Gassner (Ber. Deut. Bot. Gescil., 33 (1915), No. 4, pp. 217-232).—Discussing the tabulated results of tests with plants in widely separated families, the author emphasizes the fact that in these cases nitrogen variously combined in the nutritive media was found to show the same favorable action as did light. Some doubtful or contradictory results are reported.

Studies on light and temperature as related to the germination of seeds, G. Gassner (Ber. Deut. Bot. Gesell., 33 (1915), No. 4, pp. 203-217).—Giving the results of studies by other investigators the author reports a continuation of his own work (see above), using seeds of nine species of Onagraceæ, one of Hydrophyllaceæ, and two of Scrophulariaceæ.

It is stated that in the first group three different germination types may be distinguished as regards their relation to light and temperature. The second division is characterized by a low germinability optimum and by the injurious action of high germination temperatures, the favoring action of temperature change, and the unfavorable action of light at extreme germinating temperatures. In the third group, the seeds require stronger light at low temperatures. Temperature variations here also favor germination, especially when regular, giving the most marked results when the lower daily temperatures were maintained for longer periods than were the higher temperatures.

Influence of temperature on the moisture intake of seeds, C. A. Shull (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 329).—According to the author, a critical analysis of the data obtained as to the rate of moisture intake at various temperatures by seeds possessing semipermeable coats, shows that the

curve of intake is by no means so simple as that reported for barley by Brown and Worley (E. S. R., 28, p. 226). The temperature coefficient for the rate of intake is said to be decidedly lower than the Van't Hoff coefficient for chemical processes and considerably lower in the case of Xanthium than the values obtained with barley seeds. It is considered that the conclusions reached by Brown and Worley are not generally applicable.

Seed sterility and delayed germination in Œnothera, B. M. Davis (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 291).—From a study of 50 or more species, races, and hybrids of Œnothera, the author reports considerable seed sterility and delayed germination. A method is suggested for rapidly forcing germination and for preserving for examination the residue of sterile seedlike structures.

The influence of the medium upon the orientation of primary roots, R. M. Holman (Abs. in Science, n. ser., 43, (1916), No. 1105, pp. 328, 329).—By the use of media whose resistance to penetration by the root tip could be widely varied, the author was able to cause roots to behave very nearly as in the air or in the same manner as in the earth, according as the medium was loose or considerably compressed. These experiments are believed to indicate that the effect of the medium is primarily, if not exclusively, mechanical. Secondary roots of the species investigated behaved in a manner similar to the primary roots, reacting more promptly in media offering considerable resistance to penetration than in looser media.

The root growth of forest trees, W. B. McDougall (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 324).—Observations made on the roots of Acer saccharinum, Tilia americana, Carya alba, and Quercus macrocarpa are reported for the growing season and during the winter from April, 1914, to September, 1915.

It was found that the root growth of forest trees begins as early in spring as the soil is warm enough for absorption and ceases in autumn when the soil becomes too cold. No summer resting period was found necessary. Where a summer resting period was observed, it was found to be due to a lowering of the water supply and not to any inherent tendency to periodicity.

The influence of electrical conditions in plants on the absorption by their roots of nutritive substances, D. Shushak (Chouchak), (Zhur. Opytn. Agron., 16 (1915), No. 4, pp. 249–269, figs. 5).—In continuation of previous work (E. S. R., 32, p. 328), the author states that experimental tests as tabulated show that up to a certain point the direction and intensity of the electric current passed through a plant condition the absorption of cations and of anions and determine the rate thereof. These variations in the absorption rate are apparently independent of electrolysis, as they do not follow Faraday's law. Dead and living wheat plants give results of the same character.

These facts suggest that some substances, probably colloidal, may be differently polarized under the influence of charges of different sign and intensity up to certain limiting values. Such charges are said to be directly observable in the absence of a current by the use of a delicate electrometer and to be modifiable by the addition of salts. The variations in rapidity of absorption of cations and in intensity of current show a degree of correspondence. It is thought that the electrical conditions in the roots of plants may be of significance in plant nutrition.

The structure of the bordered pits of conifers and its bearing upon the tension hypothesis of the ascent of sap in plants, I. W. Balley (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 329).—Attention is called to the tension hypothesis of the ascent of sap in plants, which, as interpreted by Dixon, postulates continuous columns of water that are entirely free from bubbles of air or gas. The pit membranes of conifers are said to be not entire septa, and not to

be entirely impervious to undissolved gases and solids. Consequently the surface tension of the sap in the sieve-like pit membranes is not sufficiently great to prevent the penetration of air or gas under the tensile strains that are supposed to occur in tall trees.

Anatomical and physiological studies on the aquiferous vessels in plants, II, L. MONTEMARTINI (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 12 (1915), pp. 363–533, pls. 10).—('laiming to have found that the number of conducting vessels in various plants increases from below upward, especially in the neighborhood of branches, and showing also in some cases a certain relation with the development of surface in the related transpiring organs, the author gives a detailed account of his recent studies on the number and size of the aquiferous vessels and the modifications of the woody elements in relation therewith.

He sums up much of the extensive data obtained from this work by stating that the quantitative and qualitative modifications which can be noted in the wood at various heights in an organ or system of organs, and which are variously combined according to species, individual, or environment, tend on the whole to increase toward the active wood, and more particularly that part which is in more intimate relation with the vascular elements, when measured by the number of the cells which are in direct contact with such elements. Both structure and content in these regions indicate very active changes between the vessels and the cells which surround them. This becomes more and more evident as parts are examined in regions showing greater activity of the transpiration stream.

A bibliography is appended.

On the permeability of certain nonliving plant membranes to water, F. E. Denny (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 329).—A report is given of a series of experiments with plant membranes in which quantitative measurements were made of their permeability to water. The membranes used were those of the seed coats of peanut, cycad, almond, English walnut, pumpkin, bulb-scale of onion, etc. Results are reported showing the temperature coefficient for a rise of 10° C., and also showing the permeability of the membranes as affected by the concentration of the bathing medium, direction of flow through the membrane, and as influenced by certain chemical constituents of the membrane.

Studies in permeability.—II, The effect of temperature on the permeability of plant cells to the hydrogen ion, W. Stiles and I. Jörgensen (Ann. Bot. [London], 29 (1915), No. 116, pp. 611-618, figs. 4).—Reporting a continuation of investigations previously noted (E. S. R., 34, p. 731) by methods which are further detailed, the authors claim to have shown that the rate of absorption of the hydrogen ion of hydrochloric acid in dilute solution by potato cells shows a simple exponential relation between time and the concentration of the acid, the absorption rate of potato cells being increased about 2.2 times for each 10° C. rise between 0 and 30°.

The production, by use of paraffin, of hypertrophic and hyperplastic growths in shoots, E. Schilling (Jahrb. Wiss. Bot. [Pringsheim], 55 (1915), No. 2, pp. 177-258, figs. 43).—Giving an account of the anatomical and physiological effects of artificially closing the stomata, the author states that the resulting changes observable in the shoot axis are due not to any chemical influence of paraffin or vaseline but to the limitation imposed by them upon the transpiration process, and perhaps also to the corresponding limitation of oxygen access. It is stated that in the overgrown cells the osmotic pressures are various but generally higher than in the normal cells. It is claimed also that by covering the surface of the twigs with paraffin, abnormal leaves and adventitious roots may be produced.

Some factors determining the presence of fat as a food reserve in woody plants, E. W. Sinnott (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 328).—Reserve fat is said to occur most abundantly in those woods in which the rays and parenchyma cells are comparatively thin-walled and well provided with pits, and to be particularly well developed in the cells immediately adjacent to the vessels. The fat is said to be practically absent in species with thick-walled, slightly pitted parenchymatous tissue.

These facts are claimed to suggest that the occurrence of fat in wood and its distribution may depend on the easy diffusion of some fat-forming ferment. Experiments show the presence of a fat-splitting ferment in the leaves and bark, which varies greatly in amount according to species and season but which is in general most abundant in the spring in those species in which reserve fat is most abundant in winter. It is suggested that this fat-splitting ferment may be reversible in its action, and during late summer and fall it may be diffused downward through the wood and bast, converting into fat the food reserve to which it has access.

On the properties of a chromogen generally present in plants, J. Wolff and Nadia Rouchelmann (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 13, pp. 399-401).—The authors, having extended their study as previously reported (E. S. R., 34, p. 32) to a number of plant families, state that the chromogens exhibit, besides their great sensitiveness to the action of laccase and hydriodic acid, a large number of characters in common, some of which are here enumerated, indicating that they should probably be regarded as one and the same. The brown coloring matters that form in various plants or organs may be regarded as products of oxidation, as observable in case of the brown pigment of cut or injured potatoes, horse chestnut, dead leaves, and macerated green plants when subjected to the action of a laccase.

Lipolytic action in germinating teliospores of Gymnosporangium juniperivirginianæ, G. H. Coons (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 327).— A study was made of the teliospores from mature telial horns of G. juniperivirginianæ, which seemed to indicate that in the germinating spores lipase is present. This places the rust fungi in the list of organisms now known to possess lipase. Attention is called to the occurrence of oil in rust spores, and the conversion of the globules of oil into soluble products, brought about by the lipase, is considered a factor in the rapid germination process.

Acidity and gas interchange in cacti, H. M. RICHARDS (Carnegie Inst. Washington Pub. 209 (1915), pp. 107, figs. 6).—The author gives an account of the methods and results of his work as carried out with cacti at the Desert Botanical Laboratory at Tucson, Ariz., along three main lines, namely, the determination of the acidity of the tissue as regards the expressed juice and the total amount of acid present, the determinations of carbon dioxid evolution to fix the diurnal periodicity in relation to normal temperature changes and to ascertain the effects of various agencies upon the rate, and the study of the gas interchange in darkness between plants and the atmosphere. The results are given in considerable detail and discussed in their bearings.

It is stated that with rising acidity in the tissues, the total acid increases more rapidly than does the concentration of the juice. Light, the most important factor in the diurnal decrease of acidity, is less effective at the lower temperatures. Rising temperature, especially above 30° C., decreases acidity when this is initially high, but does not wholly inhibit its production. Acidity tends to decline with excess of oxygen and to increase with deprivation thereof. While excess of oxygen raises the carbon dioxid-oxygen ratio, this ratio remains stationary or decreases in its absence. Wounding causes an increase

in acidity related to its extent. The acid content does not vary greatly with age, except in very young tissue. The actual rate of carbon dioxid production is greatest in the youngest tissues, next in the old turgid joints, and least in the flaccid joints, the gas interchange ratios varying according to the acidity conditions rather than according to the age of the tissue. In general, high acidities, high evolution rate of carbon dioxid, and high carbon dioxid-oxygen ratios are associated. No difference of acidity was found between the base and the tip of the joint, but most of the acid was held in the layers of soft, highly turgid cells outside the bundle ring. Some discussion of the bearings and implications of the facts as observed is also given.

Localization of acids and sugars in fleshy fruits, E. Demoussy (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 15, pp. 443-445).—Tabulated results of analyses of the juices obtained from a number of fleshy fruits by employment of graduated pressures show that the increase of acidity and reducing sugars due to pressure, while considerable in case of a few fruits, was slight, lacking, or negative in others, so that a positive increase can not be considered as general. The variations due to pressure in case of nonreducing sugars were usually opposite in direction to those in acidity and in reducing sugars. The chemical composition of a fruit varies in different fruits in portions apparently homogeneous otherwise and in spite of the fact that they may have the same proportion of water, which appears to circulate more readily than do certain solutes.

These studies are considered to have brought out striking conformities to the law announced by Maquenne (E. S. R., 8, p. 844), according to which soluble bodies tend to accumulate at points in the living organism where there is a lowering of the osmotic pressure. This law is used to explain such phenomena as the accumulation of acid in certain portions of fruits during the process of cooking.

What are chondriosomes? D. M. Motter (Abs. in Science, n. ser., 43 (1916), No. 1104, pp. 286, 287).—In addition to the chondriosomes occurring in higher plants, which become leucoplasts in case they occur in the roots and chloroplasts when in the stems, the author calls attention to the presence in cells of certain plants of other bodies similar in structure and reaction which do not develop into either leucoplasts or chloroplasts. These bodies are said to be always present in the form of granules or delicate rods, and, as they are permanent organs, they should be given morphological rank. They do not arise from the nucleus, and the question is raised as to whether the term chondriosome should be applied to the organs under discussion.

Rapid methods for quantitative and qualitative studies on the soil flora, T. F. Manns (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 288).—For the rapid study of soil organisms, the author suggests the use of a mechanicl shaker, in conjunction with suitable media. It is claimed that where the shaker was used it was possible to plate 16 soils in duplicate plates with 2 dilutions on four different media in from $2\frac{1}{2}$ to 3 hours. Usually three media will suffice to bring out the important groups, one for the ammonifying organisms and the saprophytic forms, including molds. etc., a second for Bacillus radicicola, and a third for Azotobacter, B. radiobacter, and nitrifiers.

Media for quantitative and qualitative studies on Azotobacter and nitrifiers, T. F. Manns (Abs. in Science, n. ser., 43 (1916), No. 1104, pp. 288, 289).—In making a survey of the bacteria in various groups of soil organisms, the author found that a soil extract agar, to which was added 0.5 gm. of a mixture of insoluble salts, would bring out the nitrogen-fixing organisms and the nitrifying organisms.

Peat organisms that slowly liquefy agar, T. F. Manns (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 289).—While making a study of the flora of raw peat and muck, the author observed that certain colonies of bacteria were able to break down the agar and cause a deep pitting in the medium. The organism appears to be a micrococcus and to be most abundant in peat that is composted with ground calcium phosphate and calcium carbonate.

The transmission by maize seeds of the effects of detasseling, E. Heckel (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 12, pp. 338-340; Prog. Agr. et Vit. (Ed. VEst-Centre), 36 (1915), No. 50, pp. 570-572).—Following up his previous work (E. S. R., 33, p. 426), the author took four strains of Giant Serbian maize bred during the previous four years, the stalks being detasseled each year after the accomplishment of fertilization, and after detasseling the stalks August 20, 1915, tested them at intervals for sugar, as possibly showing the cumulative effects of traumatism on the sugar content.

Each of the four series tested, while showing an increase over its control in saccharose and a decrease in glucose, showed an increase in the total of both, the greatest percentage of total increase of these sugars being obtained from the strains previously showing only moderate sweetness, and the maximum increase being attained in 24 days after detasseling. Starch was present in all the stalks that had been detasseled.

Experiments in recombining endosperm colors in corn, R. A. Harper (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 290).—Attention is called to the fact that well-established black races of corn, when crossed with white races, give, both in the F_1 and F_2 generations, a series of colors including dark purples, reds, blues, grays, etc. The author has undertaken a series of recombination tests, but no immediate and uniform return to the ancestral black has been obtained as yet.

The chlorophyll factors in Lychnis dioica, G. H. Shull (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 290).—According to the author, three Mendelian factors are responsible for the chlorophyll of the normal dark green biotypes of L. dioica. One of these differentiates all green strains from albinos and is capable only of ephemeral existence. A second, acting in conjunction with the first, produces a form with possibly two-thirds as much chlorophyll as the normal. The third factor acts in conjunction with the other two to produce the full green color.

Orthogenetic saltation in Nephrolepsis, R. C. Benedict (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 292).—The author describes some forms of discontinuous variation in N. exaltata bostoniensis. In this variety there are said to be at least three distinct lines of variation, progressive dwarfing, progressive increase in division of leaf, and progressive increase of waviness of leaf, each variation being represented by a number of forms.

Evidences of hybridism in the genus Rubus, C. S. Hoar (Abs. in Science, n. ser., 43 (1916), No. 1104, pp. 290, 291).—The author presents morphological data considered to favor strongly the occurrence of widespread hybridism in the genus Rubus. There is believed to be good evidence from the standpoint of extreme variability and correlated gametic sterility of widespread natural hybridism in this genus.

An interesting modification in Xanthium, C. A. Shull (Abs. in Science, n. ser., 43 (1916), No. 1104, pp. 292).—A peculiar modification of burs of Xanthium is described, in which the number of the flowers surrounded by the involucre has been greatly increased. The manner in which the form originated is unknown, but it is thought to be either a mutation or a reversion from X. canadense.

Transmissibility of characters acquired by plants grown in salt water, P. Lesage (Compt. Rend. Acad. Sci. [Paris]. 161 (1915). No. 15. pp. 440-442).—The author, employing Lepidium satirum, has attempted to ascertain whether the characters acquired by plants grown in salt water and persisting in their descendants grown in the same medium for several generations, will persist also when their progeny are grown in fresh water. One year's tests are said to have given positive results and are considered to show the transmissibility by plants of characters acquired in salt water.

Pollen sterility in relation to the geographical distribution of some Onagraceæ. C. C. Foramith (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 291).—Studies have been made of species of Epilobium and Zauschneria, which represent different subgenera of Onagraceæ, to determine further evidence of interspecies crossing as found in Enothera. The results are said to show that, from a morphological standpoint, interspecies crossing is not an uncommon occurrence in this family of plants.

A remarkable new Eysenhardtia from the west coast of Mexico, W. E. Safford (Jour. Wash. Acad. Sci., 6 (1916), No. 6, pp. 133-135, fig. 1).—The author describes E. olivana n. sp., and suggests the advisability of a critical study of the entire genus.

FIELD CROPS.

[Work with field crops], L. R. Waldron (North Dakota Sta., Rpt. Dickinson Substa., 1913, pp. 5-20, 22-31, figs. 5).—The results of work with different field crops for a number of years are briefly reported.

Alfalfa gave an average yield of two tons per acre for the five years beginning with 1909, and in 1913 a seed production of 112.3 lbs. per acre was recorded. For the five years beginning with 1909, alfalfa in cultivated rows gave an average yield of 1.224 tons per acre and in 1909 a seed crop of 336 lbs. per acre was produced. Disking alfalfa after the first cutting did not give conclusive results, but indicated that with unfavorable moisture conditions the practice tends to increase the yield. Grimm alfalfa from home-grown seed proved to be more winter resistant than Chinook alfalfa from Montana-grown seed. In cultural tests conducted in 1913 the greater amount of seed was produced by the second growth and by thin stands in cultivated rows. Notes on cooperative alfalfa growing and on the results of some breeding work are given.

Cultural tests with sweet clover and sunflowers and a variety test with wheat are also recorded. Among other results with sweet clover a yield from Iowa seed of 524 lbs, of hulled clean seed per acre is noted. Sunflowers made a yield of field cured stalks and seeds of 4.356 tons per acre. This crop is considered of doubtful economic value for that section of the State. In a test of 24 varieties of wheat, Kubanka No. 8, descended from a single plant selected at the station in 1906, ranked first with a yield of 31.6 bu, of grain per acre.

Results of three trials with Girka wheat showed selected strains to be superior in yielding capacity to the bulk lot from which the pure lines were derived. In 1913 Victory, Silvermine, and Golden Rain ranked highest among 11 varieties of oats, with yields of 65.1, 64.5, and 63.4 bu, per acre, respectively. The same year Primus and Swan Neck barley were the heaviest yielders of 8 varieties, producing, respectively, 40.7 and 40.2 bu, per acre. The average yields of two 2-rowed and two 6-rowed varieties of barley grown for five years were in favor of the 2-rowed sorts by 45 per cent. A plat of Yaroslav emmer produced 53.8 bu, per acre and an adjoining plat of spring rye 21.3 bu. Experiments with wheat, oats, and barley in moisture conservation conducted from 1908 to 1913

showed that clean summer fallow had not been very profitable, especially with oats and barley.

Sixth annual report of the Williston substation for the year 1913, E. G. Schollander (North Dakota Sta., Rpt. Williston Substa., 1913, pp. 48, figs. 4).— The results are reported of tests conducted in 1913, mainly, with varieties of spring and winter wheat, oats, barley, emmer, spelt, rye, millet, potatoes, sugar beets, and alfalfa. Cultural experiments with wheat, oats, and potatoes, principally with reference to rate and time of seeding and planting, are also reported, together with a study of hardiness in different species and varieties of medicago, including alfalfa, and meteorological observations at Williston, N. Dak., during 1913 as to temperature, precipitation, and evaporation.

[Work with field crops in 1915] (Rhode Island Sta. Rpt. 1915, pp. 26, 27).—Tests of varieties of potatoes showed that Clyde was not superior to Norcross and that Enohla was as early as Irish Cobbler and more productive. Norcross potatoes grown at the station did not prove as good for seed as those grown in Maine, and nothing was gained by selecting the seed from the most productive hills, although potatoes selected for two years were superior to unselected stock. The use of 2-oz, potatoes for seed planted 18 in, apart in the row gave about the same yield as planting 1-oz, pieces 9 in, apart, but the yields decreased successively when ounce pieces were dropped 12 and 15 in, apart.

Among several varieties of sweet corn planted April 28, a special strain of Early Cory produced the first pickings August 6 and 9 and yielded about 50 per cent more than commercial seed. The number of dozen ears secured on a given area by the different varieties on and before August 13 was as follows: Golden Bantam, 8; Crosby Early, 41; Quincy Market, 75; Early Cory, 99; Early Cory, special strain, 129. Experiments with three strains of White Cap corn showed no decided difference in yield between the three strains and three crosses from the same.

A yield of 30 bu, of Red Chaff winter wheat was recorded. Mammoth White Rye from Canada was not found superior to Excelsior. Sudan grass planted May 11 in drills 2 ft. apart grew fairly well on acid soil, and when allowed to stand until September 3 yielded 11.5 tons of green material. Mixing a liberal amount of hydrated or slaked lime with the surface soil and subsoil gave no larger yields of alfalfa than where such lime was mixed only with the surface soil. Alfalfa cut on June 1, July 19, and September 14 yielded a total of 4.24 tons of hay per acre as compared with 4.5 tons cut on June 24, August 14, and September 14. A mixture of orchard grass and alfalfa seeded in 1912 yielded 4.2 tons of hay as compared with 4.34 for alfalfa alone.

Crop rotations for upper Wisconsin, E. J. Delwiche (Wisconsin Sta. Bul. 222 (1916), 2. ed., pp. 26, figs. 16).—The first edition of this bulietin has been noted (E. S. R., 28, p. 40). The additional statements presented point out that pasturing the first crop of clover for about two weeks in early spring, or until June 10, retards the time of cutting but without greatly affecting the yield, that in a 3-year rotation for dairy farms manure may be applied on new clover fields in the fall or winter, and that in other rotations corn and potatoes should not follow each other.

Experiments with corn, C. F. Noll (Pennsylvania Sta. Bul. 139 (1916), pp. 23, fig. 1).—These experiments included trials of varieties grown for grain and for silage, tests of selection and care of seed, and breeding work, mainly ear-to-row selection, inbreeding and crossing inbred strains, and crossing varieties. The results of the variety tests are regarded as applicable only to sections of the State with conditions similar to those existing at the station.

For central Pennsylvania, the northern counties with an altitude not quite so great as that of the station, and for the higher altitudes of the southern counties, Minnesota 13, U. S. Selection 133, 90-Day Clarage, Murdock Yellow Dent, Wisconsin No. 7, and Holmes White-Capped Yellow Dent, varieties grown for grain, and 100-Day Bristol and Reid Yellow Dent, varieties suited for silage, are recommended for trial.

In the selection and care of seed only ears showing perfect germination were planted, and yields were secured from perfect stands. Seed selected on the stalk germinated better than seed selected at husking time in an indoor test in the single year for which the record was kept, but the seed selected at husking time in the three years' trials gave the better field germination, and there was not much difference in the yields. Heavy seed gave a little better field germination and a somewhat better yield than light seed. While seed from ears germinating quickly gave the better field germination, the difference in yield was within the limits of error. Keeping the seed at living room temperature during the winter resulted in better germination indoors and in the field than was obtained with seed kept without artificial heat, but the difference in yield was insignificant.

Ear-to-row breeding of one variety followed by crossing of remnants of the best yielding ears, as shown by yields of seed from the best ear rows and from crosses of the best ears, did not materially increase the yield. Inbreeding very much reduced the size of stalks and yield, while crossing of inbred strains not closely related restored the vigor and productive capacity. Of eight first-generation crosses only two outyielded the better parent, the difference in yield being but little.

The development and properties of raw cotton, W. L. Balls (London: A. & C. Black, Ltd., 1915, pp. XII+221, pls. 16, figs. 22).—The main purpose of this book, it is stated, is to present the history of the development of cotton-lint and, accessory to this purpose, to indicate the development of the plant on which this lint is borne. The chapters presented discuss the development of pedigree, the growth of the cotton plant and the factors which affect it, the structural development of the boll and how this may be influenced by environment, the production and preparation of commercial lint, the growth of cotton culture, and the methods employed in studying and improving the crop. Tables of statistical data are appended.

Note on the classification of the rices of Lower Burma, R. A. Beale (Reprinted from Poonu Agr. Col. Mag., 7 (1915), No. 2, pp. 10).—Schemes of classification proposed by Kikkawa and Graham among others are briefly discussed, and the botanical characters of rice important in the classification of varieties are enumerated and described. Agricultural characters in themselves are considered an inadequate basis for classification, as they are affected by environment but are regarded of value in this connection only when used in conjunction with botanical characters. A tentative scheme for the classification of the rices of Lower Burma is proposed.

The culture of rice in Spain, H. Jumelle (Inst. Colon. Marseille Bul. 1 (1914), pp. 28, fig. 1).—This bulletin is a popular discussion of the ordinary field practice in the culture of rice as applied in the Province of Valencia in Spain. Statistics of production and marketing are also given.

Annual report of the Bureau of Sugar Experiment Stations, E. G. E. Scriven (Ann. Rpt. Bur. Sugar Expt. Stas. [Queensland], 1915, pp. 52).—This report reviews the progress of the cane-sugar industry of Queensland and the production of cane and sugar in 1915. The experimental work carried on at the Central Sugar Experiment Station at Mackay, the Southern Sugar Experiment Station at Bundaberg, and in other parts of the State, is briefly noted.

Experiments were conducted to determine the best system of treating rations. The different treatments included leaving the trash on the ground and allowing the cane to volunteer, burying the trash between the rows, shifting the trash in every other space between the rows and cultivating the cleared spaces, and burning the trash and opening the middles with plow and subsoiler to a depth of from 16 to 18 in. Under the conditions of a severe drought, leaving the trash gave the best results, but the preceding year, when conditions were normal, burning the trash and giving deep cultivation, which is the station method, proved most profitable. It is concluded from the results that plowing under trash in the rations does not pay.

The results of a variety test showed that Q 813 ranked first in sugar content followed by Q 990 and Q 137. Experiments with canes from the Queensland Acclimatization Society were continued and the second ration crop was harvested. Badila Seedling and Hybrid No. 1 gave the highest percentage of pure, obtainable cane sugar.

Different cultural methods compared resulted in the highest total yield of plant crop of 1914 and the first ration crop of 1915 on the plat giving shallow cultivation with broad hoes and on the one cultivated with a light drill harrow fitted with straight sharp tines. In a test to determine whether cane sets cut from arrowed canes have a prejudicial effect on the germination and subsequent yield, it was found that the cane from arrowed cane sets not only produced a greater stand of cane but also a greater yield.

Analytical tests to determine the commercial value of a number of generally grown varieties showed that HQ 426 and Badila gave much better yields of pure obtainable cane sugar than Goru, Cheribon, Malabar, and Otamite. Early or late planting apparently had no effect on the average sugar content of Cheribon, Malabar, and Otamite, while in the other three varieties the late planting gave better average analyses. In a second test HQ 426 and Badila also ranked first.

The Mackay station laboratory reported tables of analyses showing the quantities of lime, potash, phosphoric acid, and nitrogen removed in crops of cane of the weight grown. It was shown that more potash is removed than nitrogen, lime, and phosphoric acid.

At the Southern Sugar Experiment Station at Bundaberg, planting cane in rows 5, 6, or 7 ft. apart showed that the closer planting produced the better yields. It was further found that planting tops only gave much better results than planting middles or bottoms and middles. The results of cultural tests were in favor of subsoiling but the cost was too high to be profitable. Cane volunteered through trash, owing to a dry season, gave the largest margin of profit, but this method is not advised as under normal conditions cultivation usually gives much better results. Analyses of burnt canes indicated that the cane did not depreciate to any extent during the first 48 hours, after which the glucose content began to increase rapidly until the tenth day, when it had increased almost twenty times as much as in the original. The loss in weight of cane and in the purity of the juice was also considerable.

Planting sprouted cane cuttings, J. SCHUIT (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 12, pp. 461-466; Meded. Proefstat. Java-Suikerindus., 5 (1915), No. 5, pp. 178-182).—This article describes the method of planting sugar cane with cuttings in which the buds have made some growth, as distinguished from the usual method of using cuttings in which the buds have not yet started. Directions are given for the production of cuttings and for handling, treating, and planting them.

Sweet potato culture for the southern planter, C. Crow and C. W. WAUGHTEL (Seville, Ga.: Crow & Brogdon, 1915, pp. 103, pls. 12, fig. 1).—A popular treatise on sweet potato culture, including descriptions of the various phases of the work and devoting a chapter to commercial sweet potato plant growing in Florida.

Timothy: Its history, culture, and variability, and breeding work carried on with the plant at Svalöf, H. WITTE (Sveriges Utsädesför. Tidskr., 25 (1915), Nos. 1, pp. 23-44; 4, pp. 143-182; 5, pp. 199-221, figs. 26).—This article presents historical and cultural notes regarding timothy, reviews breeding work with the plant carried on in different countries, discusses its different forms, describes the technique and the method employed at Svalöf in breeding perennial grasses, particularly timothy, and reports results secured together with deductions drawn from them. It is pointed out that since timothy is crossfertilized and is also very variable, it is impracticable to base its improvement on the selection of homozygous individuals.

In the breeding work it was found that in length of stem the plants varied from 20 cm. to over 100 cm. The heritability of the length of stem was indicated by the experimental results. The number of internodes varied only from 5 to 7 but in length the internodes showed great variations. In some forms the upper internode constituted more than half and in others only one-fourth of the stem length. The lower internodes were quite short in some cases and in others comparatively long. The thickness of stem varied for the different forms but no correlation with the length of stem was established. The shape or form of the stem was found to vary to a considerable extent and appeared to be a heritable character.

Most forms showed a habit of stooling densely, but some stooled quite loosely due to the development of culms from the leaf axils of the preceding generation of sprouts. The leaves varied in length and width and also in shape, some forms having soft and pendant blades while in others the blades were stiff and erect.

The spike in the different strains ranged in length from about 2 to 15 cm. and in thickness from approximately 4 to 10 mm. Correlation between length and width of spike and between length of spike and stem was not established. The spike was generally cylindrical but forms with the greatest diameter either at the base, the point, or the middle were found. In some forms the spike was loose and pendant, while in most cases it was stiff and erect with the spikelets densely set. The spikelets in certain strains were not entirely united with the central axis of the spike, which gave to the head a rough or minutely branched appearance. This also proved to be a heritable character, but the author points out that from a practical standpoint the length and density of the spike are mainly of value.

The floral parts and the fruit also presented many variations. At Svalöf no differences in winter resistance were observed but in the extreme northern part of Sweden marked differences in this respect were found to exist. Variations were also determined in regard to sprouting, time of blossoming, strength of culm, time of withering of leaves, quantity and quality of second growth, rust and drought resistance, and the length of the period of productiveness. The degree of adherence of the glumes to the ripe seed varied with the different forms and the practical bearing of this character is dwelt upon. The characters of strains of timothy requisite for profitable temporary and permanent meadows, and for satisfactory seed and forage production, are enumerated.

The results of tests with new strains of timothy showed that No. 237a, or Primus, produced a yield 16.7 per cent greater than commercial sorts, while No. 217 yielded 6.7 per cent more than Primus.

Tobacco seed beds, F. Charlan (Canada Expt. Farms Bul. 21, 2. ser. (1915), pp. 51, pls. 3, figs. 13).—This bulletin is a popular treatise on the preparation, care, and management of tobacco seed beds. Detailed temperature records of hotbeds, semihotbeds, and greenhouses are appended.

On the inheritance of some characters in wheat, II, A. and G. L. C. Howard (Mem. Dept. Agr. India, Bot. Ser., 7 (1915), No. 8, pp. 273-285, pls. 9).—In previous work along this line (E. S. R., 28, p. 638), it was assumed in view of the results secured that in the crosses between bearded and beardless wheats the bearded parent had two factors, one capable of producing short awns or tips only and the other, when acting in conjunction with the first, resulting in fully bearded plants. To obtain further data on the subject the cross was continued to the F4 generation, in which the behavior of selected plants confirmed the results of the third generation. The forms with long tips and short tips as well as the bearded and beardless plants bred true.

For the further study of these factors short-tipped and long-tipped forms isolated from the F_4 of a cross between P 22, containing the two factors producing the fully bearded character, and A 88 (entirely beardless) were recombined, and P 6, a wheat apparently carrying the long-tipped factor, was crossed with P 7 which seemed to have short tips. In the recombination of the bearding factors of P 22, the F_1 plants were almost beardless while 59 plants in the F_2 ranged from 4 beardless to 4 fully bearded. In the cross of P 6 with P 7 the procedure was the same and the results were similar.

Two other cases of a cross between a bearded and a good beardless form were studied. Punjab Type 9, a bearded wheat, was crossed with Pusa 4, an entirely beardless form, and in the F₂, 610 plants were examined. Of these, 39 were beardless and 571 were awned to varying degrees ranging from fully bearded to minutely tipped. Similar results were obtained in crossing BXI 77, a fully bearded form, with Pusa 4. The ratio of bearded to beardless forms is regarded as indicating the existence of two factors in the bearded parent.

It was observed that the development of a bearded or beardless character was not always uniform, especially in the case of cultures breeding true to long or short tips. The first formed and largest ears had the longest awns, while those produced later had almost no awns. It is stated that well-grown cultures develop tips normally and present no difficulty in deciding whether the tips are long or short, while in weaker growth the tips do not develop well and care is necessary to distinguish their nature. It is further found that observations on bearding are best made when the ears are still green and just before the chaff begins to change in color. In order to grow complete cultures from any particular plant it is advised to sow the grain in boxes and then transplant the seedlings into the field, as in this way little or no loss of plants occurs.

Studies were also made of felted and smooth chaffs as heritable characters. A microscopical study of the chaff of Punjab Type 9 revealed long silky hairs and much shorter ones. An analysis of the F_3 and subsequently of the F_2 generation resulted in the isolation of these two kinds of hairs and in the proof that each kind is inherited separately. Three crosses were made which resulted in the proof that the felting in Pusa 4 is identical with that in BXI 77 and that the felting in both these cases is identical with the short chaff hair character in Punjab Type 9.

Some observations on the occurrence of sterile spikelets in wheat, A. E. Grantham (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 6, pp. 235-250, pl. 1; abs. in Science, n. ser., 43 (1916), No. 1104, pp. 289, 290).—The results of an examination of a large number of varieties of wheat with reference to sterility of spikelets made at the Delaware Experiment Station in 1915 is noted.

It was found that the varieties grown under field conditions exhibited a higher percentage of sterile spikelets than where the plants were grown 6 in. apart each way as under the centgener method. The average number of sterile spikelets in 25 spikes of each variety and the percentage to the whole number of spikelets were determined for 80 beardless and 108 bearded varieties of wheat. The average percentage of sterile spikelets in the bearded varieties was found to be 24.1 per cent, while the beardless averaged 17.8 per cent. Only 20 of the 80 beardless varieties had more than 15 per cent of sterile spikelets, while not a single variety of bearded wheat had less than 17 per cent. Forty-five of the 108 bearded varieties had 25 per cent or more sterile spikelets, while of the 80 beardless varieties only 2 had 25 per cent.

A study of a bearded and a beardless variety planted at 7-day intervals from September 17 to October 22 on fertilized and unfertilized soil showed that the earlier planting, regardless of soil fertilization, had a higher percentage of sterile spikelets than the later seeding. In this case also the bearded variety had the higher percentage of sterile spikelets.

Two varieties of wheat fertilized with different combinations and quantities of plant food exhibited considerable variation in the sterility of the spikelets. Phosphoric acid and potash used singly developed a higher percentage of sterile spikelets than nitrogen where two of the plant-food elements were used in combination. Nitrogen and potash showed the smallest percentage and phosphoric acid and potash the highest. The untreated plats were comparatively very low in the percentage of sterile spikelets produced.

Correlation studies indicated that the longer the spike the greater the number of sterile spikelets is likely to be.

HORTICULTURE.

Horticultural investigations.—A retrospect, L. C. Corbett (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 64-70).—A short retrospect of horticultural investigations in the United States. The various lines of endeavor are grouped into the following general classes and discussed: Theoretical considerations, systematic studies of horticultural groups, variety tests, descriptive expositions, surveys of a statistical or economic nature, and special industrial problems.

Some problems connected with killing by low temperature, W. H. CHANDLER (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 56-63).—A discussion of the cause and nature of killing of plant tissue by low temperature, with special reference to injury to cruit trees. A bibliography of cited literature is included.

Hotbeds and cold frames, C. S. Adams (Kentucky Sta. Circ. 11 (1916), pp. 3-22, figs. 13).—Popular directions are given for the construction and management of hotbeds and cold frames.

Spraying calendar, E. P. Taylor and M. A. Willis (*Idaho Sta. Circ.* 1 (1916), folio).—This calendar contains directions for the control of the more important insect pests and plant diseases, together with formulas for the preparation of the principal sprays.

The farm vegetable garden, A. G. B. BOUQUET (Oregon Sta., Bien. Rpt. Hood River Sta., 1913-14, pp. 33-39).—Practical suggestions are given for the construction and management of a hotbed, together with suggestions relative to the production of various vegetables including varieties recommended for general use and for canning.

Preliminary report on celery storage investigations, H. C. Thompson (*Proc. Soc. Hort. Sci., 11* (1914), pp. 19-18).—A test of different types of crates as influencing the keeping quality of stored celery indicates that in order to lengthen the storage period for celery it is desirable either to use crates much

narrower than the standard crates or to furnish a ventilating partition through the center of the standard crates. The narrow crates gave somewhat better results as to keeping quality than the ventilated crates. The limit of keeping quality for celery packed in standard crates and stored under the best conditions is given as 2.5 or 3 months, as compared with at least 4 months for the small or ventilated crates. Aside from their superiority as regards keeping quality small crates are also recommended because of their ease of handling and greater durability in transportation.

Temperature readings taken in five cars of celery en route to market show that there is quite a difference in temperature at different heights in the car, both in the ends and in the center. There is also quite a difference in temperature between the ends and center of the car and between the air and celery temperature at the same location. The temperature records are so similar to those secured with fruit in transit that the author believes precooling will prove just as valuable in preventing decay in the shipment of vegetables as in the shipment of fruit.

The temperature records secured during the past two years and observations in a large number of storage houses during the past three years have led the author to conclude that celery is never inactive while in storage. Normal maturing processes go on in storage even at a temperature of 31 or 32° until the celery is ripe. Decomposition then commences and never stops until the celery is completely decomposed. Where the temperature is maintained between 30 and 32° the rate of ripening and decomposition is slow. With higher temperatures or with fluctuating temperatures the storage period is much shorter.

Fertilizer experiments with kale, T. C. Johnson (*Proc. Soc. Hort. Sci., 11* (1914), pp. 18-24).—A progress report on experiments under way at the Virginia Truck Experiment Station (E. S. R., 30, p. 532) to determine the best methods of treating truck lands in the vicinity to maintain their fertility.

An investigation in tomato breeding, F. S. Reeves (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 24-26).—A brief statement of results secured the first year in an attempt to cross the tomato with *Solanum balbisii* to get a frost-resistant tomato suitable for conditions in Ontario.

Study of the inheritance of size and productiveness in pedigreed strains of tomatoes, C. E. Myers (*Proc. Soc. Hort. Sci., 11 (1914), pp. 26-33*).—Initial selections from a number of varieties of tomatoes were made in 1911 with the view of studying the inheritance of size and productiveness. The present paper comprises a study by the statistical method of a number of plant selections within the variety Earliana. Although the experiment has not been conducted sufficiently long to warrant definite conclusions, it is believed that the data presented indicate the feasibility of improving the tomato crop by careful selection.

See also a previous note (E. S. R., 34, p. 146).

Horticultural investigations, C. I. Lewis (Oregon Sta., Bien. Rpt. Hood River Sta., 1913-14, pp. 25-33).—Notes are given on some orchard fertilizer experiments in which the ingredients are being applied both in the dry form and in solution. No definite conclusions are drawn from the results, which represent only one year's work. The data thus far secured indicate, however, that orchard trees may be benefited by spraying with certain fertilizer solutions. In one experiment, here noted, spraying with a solution of nitrate of soda and caustic soda resulted in a better color of foliage, as well as a better growth of fruit and wood, than on plats where nitrate of soda was broadcasted dry or sprayed on the ground in solution. An increased yield of fruit and a decrease in the number of the smaller apples were also observed on the trees sprayed with

the solution. The increase in size of the apples was accompanied by an apparent dropping off in color.

Experiments have been conducted for three years, in which alfalfa and clover were grown as orchard shade crops. The results thus far secured, although not decisive, suggest that where irrigation is done well and a sufficient amount of moisture is maintained in the soil trees will improve in vigor where alfalfa or clover is grown among them. On the other hand, in the absence of sufficient moisture the shade crops will use the moisture at the expense of the trees.

Further results with dynamite for tree planting, A. J. Farley (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 127-130).—The author gives additional data secured in planting apple and peach trees with dynamite (E. S. R., 32, p. 535), together with the results secured from planting pear trees with dynamite.

Summing up the results secured during the past three years, it is found that with peach trees planted at Vineland by the use of dynamite there has been a noticeable advantage in the amount of branch and twig development over trees set in the usual manner. With the exception of the first season there has been a corresponding advantage in the circumference of the trees. A similar advantage in branch and trunk development of peach trees planted with dynamite at New Brunswick observed during the first season has not been maintained during the second and third seasons. On the contrary, the advantage is now in favor of the undynamited trees. The only variety producing a profitable crop during the third summer was the Carman. The crop of this variety showed sufficient increase in favor of dynamiting to be worth more than enough to pay for the cost of the dynamite used in planting. This was not true in the case of the varieties Stump and Elberta.

The difference in twig and trunk circumference has not been so great with apple trees as with peach trees. Pear trees after two years' growth showed a slight advantage in favor of dynamiting. Trees planted with dynamite have developed a deeper root system than trees planted by ordinary methods. The cost of planting trees with dynamite was from 4 to 5 cts. per tree greater than the cost of ordinary planting.

Summing up the experiments as a whole, it is concluded that in the majority of cases the increased growth and fruit production recorded on dynamited trees is not great enough to make up for the increased cost and danger involved in planting. The use of dynamite is not recommended for tree planting on those soils that are naturally adapted to orcharding.

Report of committee on score cards, W. H. Alderman (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 43-52).—The present report represents the findings of the committee on score cards of the Society of Horticultural Science, with special reference to ideal sizes for exhibition purposes for the several varieties of apples grown in the United States and Canada.

The study of apple tree characters and its bearing on variety substitution, J. K. Shaw (*Proc. Soc. Hort. Sci., 11* (1914), pp. 120-127).—This comprises a brief survey of some of the tree characters of apples that are of value in identifying varieties, together with descriptions of a number of varieties of apples intended to apply to trees from the age of two to five or six years as they appear during late summer or early fall.

Factors correlated with hardiness in the apple, F. W. Allen (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 130-137).—The author reports studies of twigs representing varieties from several sections of the United States and Canada, but chiefly from a small nursery planted for this purpose on the Iowa Experiment Station grounds. About 33 varieties were included in the test.

Observations made relative to the factors of maturity and water content show that the hardiest varieties mature their wood from a few days to several

weeks ahead of the less hardy sorts. The hardier varieties function during the growing season with a smaller amount of water in their tissues. During a spell of very severe weather they retain their more concentrated cell sap and are not dried out so readily by the continued cold. By taking notes on maturity and making tests to determine the rate of transpiration and the freezing point of the cell sap, the author believes that a pretty accurate idea of the tree's hardiness can be obtained.

Studies of the structure and composition of the wood suggest that there is some correlation between the thickness and structure of the bark and the rate of evaporation, although the figures obtained from a large number of examinations are not conclusive. In some cases the maximum thickness of the bark of the more tender varieties exceeded the minimum thickness of bark of the hardier varieties. The amount of stored food contained in the twigs appeared to bear some relation to hardiness, although exceptions were noted. Observations relative to the size of the blossoms indicate that none of the varieties possessing large size and thickness of petals is tender. On the other hand, hardy varieties do not always have the thickest petals. Tests made relative to density of wood, although not conclusive, indicate that there is some correlation between density and hardiness.

Freezing tests were conducted to determine, if possible, the temperature at which the various varieties would be injured under a given condition and also to determine the relation between the moisture content and the ability of the twig to withstand cold. The results secured with a number of varieties are given. In general the twigs were found to be either killed or seriously injured when suddenly subjected to a very low temperature, even though it was for a short time. A longer period of moderate cold slightly injured the hardier varieties and killed most of the tender varieties.

The relation of climate to varieties of apples, R. M. Winslow (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 137-148).—The author presents data showing the main features of the growing seasons of different sections of British Columbia, including temperature and rainfall observations and notes on the adaptability of the more important varieties of apples to climatic conditions in the different sections.

A preliminary consideration of one phase of meteorological influence on plants, indicated by hand pollination of several commercial varieties of apples, W. F. FLETCHER (Proc. Soc. Hort. Sci., 11 (1914), pp. 116-119).—During the 6-year period, 1905 to 1910, the author conducted hand pollination tests in an orchard in the Shenandoah Valley with several commercial varieties of apples in different combinations of meteorological conditions. The results from this work led him to the following conclusions, which are here presented to indicate a line of research which has received little attention:

"The sterility or fertility of apple blossoms depends largely upon local conditions. In this statement due allowance is made for the tendencies of different varieties toward light or heavy crop setting character or productivity. The affinity between two varieties is governed by local conditions immediately attendant on pollination. Periods of rapid evaporation, that is, high temperatures, strong winds, and dry air at the time of receptivity of the stigmas are detrimental to the setting of fruit. The shock or the effect of undue exposure to the pistils previous to their natural opening or at the time of receptivity is so great and varies so much under slight changes of atmospheric conditions as to negative all comparative work in hand-manipulated cross pollination."

Osmotic relationships and incipient drying with apples, W. H. CHANDLER (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 112-116).—The results are given of some preliminary experiments conducted by the author and A. J. Heinicke relative to incipient drying of both leaves and fruit of the apple.

The data secured show a fairly large incipient drying in the leaves of apples and an appreciable incipient drying in the fruit. The incipient drying shows earlier with the leaves than with the fruit, and the leaves recover moisture under favorable conditions much faster than the fruit. Moisture determinations of detached and attached fruits show conclusively that the loss of water from the fruits was due to its being drawn from the fruits toward the leaves rather than to evaporation. Although the author does not consider the effect of large leaf surface in drawing water from the fruits at times to be a determining factor so far as size of fruit is concerned, it is suggested that this effect may enter as one of the many possible sources of error in the interpretation of experiments dealing with orchard culture problems.

Experimental results in young orchards in Pennsylvania, J. P. Stewart (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 101-111).—The substance of this paper has appeared in a subsequent bulletin of the Pennsylvania Experiment Station (E. S. R., 33, p. 238).

A fertilizer experiment with peaches, C. A. McCue (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 86-91).—A progress report on a long-time experiment with peaches being conducted at the Delaware Experiment Station to determine the effect of certain plant food elements upon the physiology of the tree. At the time of this report the experiment had been running for seven years.

Observations that have been made of the effect of different fertilizing elements upon color of fruit led to the tentative conclusion that any effect of nitrogen, potash, or phosphoric acid upon color is secondary. For example, the deficiency in color in plats heavily fertilized with nitrogen is attributed to the profuse growth of foliage shutting off the light rather than to the direct effect of the nitrogen. The potash plats had practically the same intensity of color as the check plat. Heavy applications of phosphoric acid appear to have a somewhat deadening effect upon color without decreasing the actual amount of color. Trees that were treated with nitrogen or combinations of nitrogen and potash are characterized by their general thriftiness.

Tests thus far made with reference to the keeping quality of the fruit from the various plats indicate that potash has some beneficial effect in increasing the period of soundness of the fruit. Heavy phosphoric acid applications delayed ripening about two days and potash hastened it one day. Nitrogen either in combination or alone delayed ripening from a week to ten days. With combinations of nitrogen and potash the retarding effect of the nitrogen is dominant. Observations thus far made do not show any effect of fertilizers on the time of blooming. The results relative to the effect of fertilizers upon the time of wood ripening in the fall are inconclusive but indicate, contrary to common opinion, that heavy applications of nitrogeneous fertilizers do not make a soft immature wood. It is suggested that the regulation of the soil moisture has a more intimate connection with fall ripening of wood and bud than does plant food. As in the case of color of fruit, light appears to be the most important factor influencing the color of twigs. Although no definite conclusion can be made at this time, tests made for several years of pollen from the various fertilizer plats suggest that plant food does have an effect upon the viability and longevity of the pollen.

Data are given showing the calculated yields per acre from the different plats during the three years, 1912 to 1914. Heavy applications of nitrate of soda have been beneficial to fruit production. Still better results have been

secured where potash was combined with nitrogen. Records of costs and receipts from the various plats show in brief that the larger the amount of nitrogen used per acre the greater were the financial returns upon the investment.

The effect of certain mineral fertilizers upon strength of wood in the peach tree, C. A. McCue (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 113-118).—In connection with the above noted experiment tests were made to determine the effect of certain plant food elements upon strength of wood in peach trees.

The results thus far secured have failed to throw very much light upon the influence of nitrogen, potash, and phosphoric acid in strengthening or weakening wood structures. Almost as much variation was found in the strength of wood from any one block of trees as in the averages for the different blocks. The author is of the opinion that even greater differences in strength of wood can be obtained by different pruning methods than were obtained by different fertilizer treatments.

Methods and results in grape breeding, R. D. Anthony (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 81–86).—The author discusses some of the points observed in the course of breeding investigations conducted by various investigators during the past 25 years at the New York State Station and summarizes some of the more important results secured in these investigations. The results of the work have been similarly summarized in a paper previously noted (E. S. R., 33, p. 641).

Recent work with Vitis vinifera in New York, U. P. Hedrick (Proc. Soc. Hort. Sci., 11 (1914), pp. 77-81).—Experiments started at the New York State Station in 1911 with 101 varieties of European grapes have shown that many varieties of the European grape can be grown in the eastern United States, providing they are grafted on phylloxera-resistant stocks and given winter protection.

Two methods have been employed in protecting the grapes. In one the vines have been covered with a few inches of earth; in the other the vines have been wrapped with straw. The earth covering was the cheapest and most efficient method.

Of 85 varieties of *V. vinifera* now fruiting on the station grounds a considerable number are here listed as worth trying on a larger scale. In view of the larger yields secured from European grapes as compared with our native grapes, attention is called to the desirability of carrying on experiments with special reference to the cultural requirements of *V. vinifera* in eastern America.

Growing and grafting olive seedlings (California Sta. Bul. 268 (1916), pp. 303-326, figs. 14).—This bulletin consists of two parts.

I. Growing olive seedlings, F. T. Bioletti and W. F. Oglesby (pp. 305–321).—
The results are given of experiments conducted to determine a method of separating good seed from poor, the best preliminary treatment of seed to facilitate germination, and the best conditions of planting to promote quick and uniform germination. Most of the germination tests were made with the Redding variety. Based on the results as a whole, a simple and rapid method of raising Redding seedlings for grafting stock is recommended in substance as follows:

The perfectly ripe fruit should be soaked in a 3 or 4 per cent soda lye for several hours to soften the skin. After washing off the lye the pulp can be removed by rubbing through a wire sieve of $\frac{3}{16}$ in, mesh. The clean seed is placed in a 25 per cent brine solution and all floating seed rejected.

Of various methods tested for facilitating germination clipping the apex or pointed end of the seed has given the best results. This is done with a clipper specially designed to prevent injury to the seed. The clipped seed is planted about 0.125 to 0.25 in. deep directly in flats containing a light porous soil, the surface of the soil being covered with a light layer of sifted moss or similar material.

The planted flats are watered only sufficiently to prevent a complete drying out of the layer around the seed. The warmer they are kept the more rapidly the seed will germinate and grow. Some of the seedlings come up in four or five weeks, others continue to come up for two, three, or more months. The seedlings are transplanted into beds at the end of about five months, or when they are about 4 or 5 in. high.

The potted seedlings are kept in a greenhouse, lath house, or other protected place until the following spring when they can be planted in the nursery. They may be budded in the autumn or grafted the next spring.

II. Grafting olive seedlings, F. T. Bioletti and F. C. H. Flossfeder (pp. 322-326).—The results are given of experiments conducted to determine a good method of tying, waxing, and covering nursery grafts. The method giving the best results consisted in tying the grafts with a cotton string without waxing and covering with soil to the top of the scion. When the grafts were covered deeply waxing proved to be detrimental.

Heredity studies with the carnation, C. H. Connors (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 95-100, fig. 1).—A discussion of the results secured in the author's breeding work at the New Jersey Experiment Stations.

The work thus far conducted shows "that in crossing a yellow carnation with white, red being present as a latent character, white is dominant over yellow and red. In the second generation, yellow will be dominant over red unless the red be strongly evidenced, in which case red is dominant over yellow. In some yellow carnations the presence of red is associated with the presence of perfect sexual organs. The probability of two kinds of white, homozygous and heterozygous, as dominants is strongly suspected."

The humidity factor in rose culture, M. A. BLAKE (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 92-94).—The substance of this paper has been included in a subsequent bulletin of the New Jersey Experiment Stations noted (E. S. R., 34, p. 44).

FORESTRY.

Michigan manual of forestry.—II, Forest valuation, F. Roth (Ann Arbor, Mich.: Author, 1916, vol. 2, pp. V+171, figs. 7).—The present treatise on forest valuation comprises part 2 of the author's manual and text-book of forestry (E. S. R., 32, p. 46). The introductory chapter discusses the literature, scope, application, and history of valuation. The succeeding chapters treat in detail of the arithmetic of forest valuation, application of valuation, relation of capital and income in forestry, rotation, value of stumpage, damage in timber, taxation of forests, fire insurance in forestry, and right use of land.

Structural timber in the United States, H. S. Betts and W. B. Greeley (Internat. Engin. Cong., 1915, Sept. 20-25, Adv. Copy, pp. 50, pls. 2, figs. 16).—
A paper presented at the International Engineering Congress, San Francisco, in 1915, in which the author surveys the timber resources of the United States with reference primarily to structural uses. Information regarding the species of particular interest to engineers is presented, together with a summary of the data obtained by the Forest Service of the U. S. Department of Agriculture on their mechanical properties and structural values. A brief reference is also made to grading rules and commercial specifications for structural timbers.

Laboratory tests on the durability of American woods.—I, Flask tests on conifers, C. J. Humphrey (*Mycologia*, 8 (1916), No. 2, pp. 80-92, pl. 1).—The author reports results of durability tests, extending over periods of 4, 6, and 12 months, of a number of American woods.

The tests were conducted in 2-liter Erlenmeyer flasks, plugged rather lightly with absorbent cotton and capped with thin muslin which had been saturated in a dilute solution of mercuric chlorid. The test blocks were placed in the flask together with "culture blocks" and then inoculated with a culture of *Lentinus lepideus*, grown on a bean pod. The "culture blocks" were irregular hemlock blocks introduced as a medium to support a vigorous growth of the fungus in order to secure a uniform and severe infection of the test blocks.

The blocks were weighed before and after the test and the percentage loss calculated from these data.

Preservative treatment of timber, H. F. Weiss and C. H. Teesdale (Internat. Engin. Cong., 1915, Sept. 20-25, Adv. Copy, pp. 45, figs. 3).—This paper, presented at the International Engineering Congress, San Francisco, in 1915, comprises a general review of the results obtained in the United States in preserving wood. A partial bibliography of the subject, covering American practice, is appended.

The properties of balsa wood (Ochroma lagopus), R. C. CARPENTER (*Proc. Amer. Soc. Civ. Engin.*, 42 (1916), No. 5, pp. 649-679, figs. 16).—This paper shows the microscopical structure of balsa wood and also gives various tests of its transverse and compressive strength. This wood has been used in the past as a buoyancy product for life preservers and in connection with the fenders of life boats and rafts. The various tests which were made of the insulating properties of this wood indicate that it may prove of value as an insulating material.

Notes on the ancestry of the beech, E. W. Berry (*Plant World*, 19 (1916), No. 3, pp. 68-77, figs. 2).—A brief historical sketch of the beeches.

British Columbia Douglas fir (Pseudotsuga taxifolia) (Brit. Columbia Govt., Forest Branch Bul. 14 (1916), pp. 15, figs. 10).—An account of the Douglas fir, with special reference to strength values under different tests as compared with other species of structural timber.

British Columbia western soft pine (Pinus ponderosa) (Brit. Columbia Govt., Forest Branch Bul. 17 (1916), pp. 15, figs. 17).—An account of this species with reference to its distribution and habit of growth, characteristics, and uses of the wood.

Influence of the intensity of thinnings on the yield of young regular stands of spruce, E. Mer (Rev. Eaux et Forêts, 54 (1916), No. 2, pp. 45-53).—In continuation of a previous report (E. S. R. 31, p. 444) the author gives the results of thinning experiments started in 1899 in which young spruce stands received thinnings of different intensities with special reference to the effect of the thinnings on yield. The results in general indicate that both early and relatively heavy thinnings act advantageously on future yield.

Manuring experiments on rubber, B. Bunting (Agr. Bul. Fed. Malay States, 4 (1916), No. 5, pp. 125-141).—This comprises a progress report on experiments conducted to determine the influence of different manures on the yield of dry rubber as measured by yield records for a period of 11 months.

The differences thus far are too small to attempt comparative values on the effect of the manures. The use of lime in connection with the different elements has resulted in increased yields, a complete fertilizer to which lime was added giving considerable increase in yield. In addition to yield data records are given of girth increase and cost of manures.

Forest experiments on heath lands, C. Dalgas (Hedeselsk. Tidsskr., 1915, Nos. 2, pp. 21-36, figs. 13; 6, pp. 74-90, figs. 14; 8, pp. 101-114, figs. 9).—The results are given of experiments conducted in state and private plantations in the culture of different species of evergreens on heath lands.

Handling the farm woodlot, C. W. EATON (Univ. Me. Ext. Bul. 105 (1916), pp. 16, fig. 1).—This bulletin deals primarily with methods of estimating woodlot timber and of selling the timber to greater advantage.

Forest planting in Wisconsin, W. D. BARNARD (Wis. Conserv. Com. Bul. 1 (1916), pp. 34, figs. 11).—This bulletin gives an account of the reforestation work accomplished by the State and by private agencies, specific directions for reforesting land, and silvical notes on a number of important species.

Forests of Yosemite, Sequoia, and General Grant National Parks, C. L. Hill (U. S. Dept. Int., Off. Sec. [Pub.], 1916, pp. 39, figs. 22).—A popular descriptive account of forest types and species in these parks.

Treatment of the forests of Mexico, H. Burcez (Dept. Bosques [Mexico] Bol. Forest. Propaganda, 2 (1914), pp. 14, pls. 3).—This bulletin comprises suggestions relative to systems of managing Mexican forests.

Report of the forestry branch, E. J. Zavitz (*Rpt. Min. Lands, Forests and Mines, Ontario, 1915, pp. 69-89, figs. 8*).—A report on the operations of the forestry branch of the Province of Ontario for the year ended October 31, 1915. Special consideration is given to railway fire protection work.

Reports of the forestry administration for 1914 ($Skogsv\hat{a}rdsf\ddot{o}r$. Tidskr., No.~10~(1915), Bilag.~2, pp.~IV+408~figs.~27).—This comprises reports from the various districts of Sweden relative to the constitution, management, administration, and various operations on the state forests, including a financial statement for the year.

Forest protection laws and suggestions for the development of an adequate law, K. E. Kallin (Skogsvårdsför. Tidskr., No. 1 (1916), pp. 1-49, figs. 24).—This comprises a historical sketch of the forest protection laws of Sweden, together with a description of the various forestry districts and suggestions relative to the development and application of an effective forest-protection law.

Progress report of forest administration in the Jammu and Kashmir State for the year 1914–15, W. H. Lovegrove (Rpt. Forest Admin. Jammu and Kashmir [India], 1914–15, pp. II+27+LIV).—The usual report relative to the administration and management of the state forests in Jammu and Kashmir, including a financial statement for the year 1914–15. Data relative to alterations in forest areas, various forest operations, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Progress report of forest administration in the Punjab for the year 1914-15, R. McIntosh ($Rpt.\ Forest\ Admin.\ Punjab$, 1914-15, $pp.\ 3+20+LX$).—A report similar to the above relative to the administration and management of the state forests of the Punjab for the year 1914-15.

DISEASES OF PLANTS.

Miscellaneous pathological projects, H. S. Jackson and J. R. Winston (*Oregon Sta., Bien. Rpt. Hood River Sta., 1913–14, pp. 19–24*).—Preliminary reports are given on investigations of the so-called winter injury or die-back in apples, apple fruit spots and rots, mushroom root rot of apples and other trees and plants, and general observations on plant diseases.

The so-called winter injury, it is claimed, is not the result of winter conditions, but it seems probable that it has some relation with the soil and moisture conditions. All attempts to isolate an organism have given negative results, and it is thought that an improvement in the mechanical and water-holding

capacity of the soil, together with a uniform supply of moisture throughout the year, will prevent the injury.

Under the heading of apple fruit spots and rots, the authors describe bitter pit or dry rot, with which no organism has been definitely associated, Jonathan fruit spot which is said to be a serious disease of the Spitzenberg and other varieties, pink spot of Newtown apples, the cause of which has not been definitely established, and apple-tree anthracnose as a fruit rot. In this case the fungus has been definitely isolated and found to cause both forms of disease.

The mushroom root rot of apples and other trees is said to be quite serious in parts of the Hood River Valley, attacking many varieties of orchard trees and shrubs as well as garden plants. Satisfactory methods of control apparently consist of thorough aeration of the soil about the trees.

Contribution to the study of the parasitic fungi of Colombia, H. and P. Sydow (In Voyage d'Exploration Scientifique en Colombie. Neuchâtel: Mem. Soc. Neuchâtel. Sci. Nat., 1914, pp. 432-441, flg. 1).—This list contains the fungi collected by Mayor exclusive of the Uredineæ as noted on page 245. Of the 42 species listed, 11 are described as new. One of these is considered to represent a new genus and has received the name Melanochlamys leucoptera.

Parasites of cultivated plants in Argentina, L. Hauman-Merck (Centbl. Bakt. [etc.], 2. Abt., 43 (1915), No. 14-16, pp. 420-454).—Besides a discussion of diseases more or less important in Argentina, lists are given of local or more extended causes of injury or diseases of plants, including bacteria, fungl, alga, phanerogamic parasites, and Cuscuta; also lists of such enemies attacking plants according to their groupings as garden, forage, ornamental, industrial, orchard, and forest plants. A bibliography is appended.

Report of the Institute for Phytopathology in Wageningen in 1913, J. RITZEMA Bos (Meded. Rijks Hoogere Land, Tuin en Boschbouwsch. [Wageningen], 8 (1915), No. 5, pp. 249-338).—This report deals systematically in some detail with phases of loss in plant industry due to causes of inorganic, parasitic, physiological, or unknown character.

Report on injuries and diseases of cultivated plants in the Rhine Province in 1913, E. Schaffnit and G. Lüstner (Veröffentl. Landw. Kammer Rheinprov., No. 3 (1915), pp. 69).—This contains reports from Bonn-Poppelsdorf and Geisenheim separately, including, besides sections on the weather and unfavorable agencies nonparasitic in character, accounts of injury or losses due to animals or to cryptogamic parasites attacking economic plants as systematically discussed by classes.

Diseases and enemies of cultivated plants in the Dutch East Indies in 1914, A. A. L. Rutgers (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 15 (1915), pp. 45).—This discussion, besides dealing with insect pests of agricultural plants, mentions as appearing here in 1914 for the first time rice smut (Tilletia horrida), Pestalozzia palmarum on Hevea trunks, and a Diplodia attacking the roots of Hevea stumps. Under the names of the various hosts, reports are given regarding diseases affecting a considerable number of agricultural and other plants.

Injury from smoke, late frost, frost drying, and their diagnosis, F. W. Neger (*Tharand. Forstl. Jahrb.*, 66 (1915), No. 3, pp. 195-212, fig. 1).—This is an account of observations and experiments regarding leaf injury or loss as related to such factors as light, heat, darkness, fungi, sulphur dioxid, hydrochloric acid, and mechanical injuries.

The occurrence of sulphur dioxid injury to plants in the Selby smoke zone, W. W. Jones (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 398-427, pls. 5).—This report deals mainly with the occurrence of sulphur dioxid injury and of

common fungus diseases, also with such matters as the presence of insect pests, the nature of the soil, and local control methods and practices. Conditions are detailed as said to exist on a number of farms.

Conditions of plant life in the Selby smoke zone, January 1 to July 1, 1914, J. W. Blankinship (U. S. Dept. Int., Bur. Mines Bul. 98 (1915), pp. 381-397, pls. 4, fig. 1).—It is stated that as a rule three kinds of injury to plants may be produced by emanations from smelters, namely, flue dust injury, due to the absorption of poisons from the soil by the roots; acid spot injury to stems, foliage, and fruit, caused by drops of sulphuric acid, usually condensed about small particles of flue dust; and sulphur dioxid injury to foliage, or more rarely to stems or floral parts, due to absorption through the respiratory system, or in some instances through the epidermal cells. The conditions for the sulphur dioxid injury, the form most usual in this connection, are more favorable in moist than in dry weather.

The parasitism of seeds and its importance in general biology, V. Galippe (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 5, pp. 112-119).—In this report, with which some discussion is also given, it is claimed that the study of a number of flowers has shown the presence of parasites in the anther, pollen, and stigma, also in the style and ovary, of a considerable proportion of those examined. It is thought that the facts as noted may bear a relation to anomalies of germination percentages and of other kinds.

Crown gall studies showing changes in plant structures due to a changed stimulus, E. F. Smith (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 4, pp. 179–182, pls. 6).—A preliminary account is given of recent experiments with crown gall in which the author describes the effect of inoculation into the cambium, the fundamental tissue of young stems, the leaf axils of growing plants, and into leaf tissue.

As a result of his investigations the author is led to the conclusion that the immature cell, wherever it is located, carries the inheritance of the whole organism, and that what it will finally become, as it matures, is dependent upon the stimuli withheld from it or applied to it. In other words, the stimulus may be either physiological, resulting in a normal structure, or pathological, resulting in an embryonic teratoma, as when a tumor-producing schizomycete is introduced into sensitive growing tissues.

Horsehair blights, T. Petch (Ann. Roy. Bot. Gard. Peradeniya, 6 (1915), No. 1, pp. 43-68, pls. 6).—Discussion is given of the characters and habits of Marasmius equicrinis, growing only on dead tissues; M. obscuratus, apparently also saprophytic; a new species described as M. coronatus, not known to be parasitic; and some undetermined species. A fungus which has been considered provisionally as a fructification of an undetermined horsehair blight is described as Xylaria vagans n. sp.

The effect of the host on the morphology of certain species of Gymnosporangium, B. O. Dodge (Bul. Torrey Bot. Club, 42 (1915), No. 9, pp. 519-542, pls. 2).—The author has begun a study of the relation of the particular host to specific differences in the parasite in case of species of Gymnosporangium, some results from which are tabulated and discussed.

It is considered as possible that *G. fraternum* and *G. biseptatum* may be two distinct species which happen to have æcidia much alike on Amelanchier. The determination of the infection limits of these two species so far as it has been accomplished has raised the questions whether *G. fraternum* on Amelanchier goes back to the cedar as *G. fraternum*, or as *G. biseptatum*, or as both, and whether *G. biseptatum* on Amelanchier goes back to the cedar and reappears as *G. biseptatum*, or as *G. fraternum*, or as both of these forms.

Contribution to the study of the Uredineæ of Colombia, E. MAYOR (In Voyage d'Exploration Scientifique en Colombie, Neuchâtel: Mem. Soc. Neuchâtel. Sci. Nat., 1914, pp. 442-599, figs. 105).—The author lists as having been found in Colombia 158 species belonging to the Uredineæ which are included in 13 genera. Of the 83 species described as new, one is considered to represent a new genus, which has received the name Chrysocelis lupini.

Diseases of grains and forage crops, M. T. Cook and J. P. Helyar (New Jersey Stas. Circ. 51 (1915), pp. 3-8).—Descriptions are given of the principal diseases of oats, wheat, corn, barley, alfalfa, and clover, with suggestions for their control.

Control of Fusarium, I. Weidner (Illus. Landw. Ztg., 35 (1915), No. 53, pp. 351, 352, figs. 4).—Describing experiments testing some fungicides for control of Fusarium on cereals, the author states that the preparations Fusariol and Sublimoform, as furnished by the Munich Agricultural and Botanic Institute, are found to be remarkably simple, effective, and inexpensive means for control of this fungus on grain intended for seed.

Experiments in control of club root of crucifers, A. NAUMANN (Flora, K. Sächs. Gesell. Bot. u. Gartenbau Dresden, Sitzber. u. Abhandl., n. ser., 17 (1912–13), pp. 62–78, pl. 1, figs. 3).—An account is given of tests from which good results as regards control of Plasmodiophora brassicæ were obtained by the employment of a patented preparation. The favorable effects are attributed to the large proportion of lime and the loosening and aeration of the soil due to the addition of mold, without which the good effects of the lime appeared to have been considerably lessened.

Combined fungus attacks on some root crops, J. Eriksson (Ztschr. Pflanzen-krank., 25 (1915), No. 2, pp. 65-71, figs. 5).—The author gives an account of the simultaneous occurrence on kohl-rabi of Fusarium brassicæ and Pseudomonas campestris, also on beets of F. betæ and Phoma betæ.

Crown gall of alfalfa, J. RITZEMA Bos (Tijdschr. Plantenziekten, 20 (1914), No. 4, pp. 107-114, fig. 1).—This is a discussion of the earlier appearances of Urophlyetis alfalfæ in different countries, the systematic relations and biology of the fungus, and measures for protection against it, including the destruction of affected plants and soil drainage.

Common diseases of beans, M. T. Cook (New Jersey Stas. Circ. 50 (1915), pp. 2-4).—Descriptions are given of the more common diseases known to attack the bean together with suggestions for their control.

Yellowing of beets by disease, J. Vasters (Landw. Ztschr. Rheinprov., 16 (1915), No. 42, pp. 641, 642).—It is stated that over large areas of the Rhine Province both ordinary and sugar beets showed this year premature yellowing of the leaves which was particularly noticeable in certain sections named. Besides animal parasites which had visibly injured the plants in some instances, examination showed the presence of mycelium or spores of Uromyces betw. Sporidesmium (Clasterosporium) putrefaciens, Cercospora beticola, and spores of two fungi, possibly Phyllosticta betw and P. tabifica. The plants suffered more or less premature loss of foliage with corresponding decrease of product. The possible bearing of rotation, manuring, and more directly protective measures is discussed.

A bacterial disease of cassava, G. Bondar (Bol. Agr. [São Paulo], 16. ser., No. 6 (1915), pp. 513-524, figs. 4).—A description is given of a serious stem disease of Manihot palmata, ascribed to Bacillus manihotis, which causes a form of subcortical gummosis, wilting, and, in case of young plants, death in the majority of cases. The disease, it is thought, may be transmitted by insects, also by tools. Of the three varieties of M. palmata discussed, one shows considerable resistance while another is very susceptible.

No curative treatment is known. Preventive measures include the use of stock and soil known to be free from the disease, selection of resistant varieties, control of insect parasites, and care in cultural operations to prevent injury to the plants and transference of the organism.

Leaf scorch, scab, and gray mildew of cucumbers, O. Appel (Deut. Landw. Presse, 42 (1915), No. 85, pp. 728, 729, pl. 1).—This contains descriptions of the respective effects on cucumber of Corynespora melonis, Cladosporium cucumerinum, and Botrytis cinerea, with some discussion of conditions and means of their communication. Control measures include the employment of only sound seed with good cultural conditions, and destruction of diseased plants.

Control of Corynespora, the cause of leaf scorch of cucumbers, OBERSTEIN (Illus. Schles. Monatschr. Obst, Gemüse u. Gartenbau, 4 (1915), No. 4, pp. 41-43, flgs. 2).—The author presents some information collected regarding the history, effects, and control of the Corynespora disease of cucumbers, the control measures including the avoidance of suspected soil, seed, or plant rubbish, and disinfection of the seed bed with formalin.

A physiological study of certain strains of Fusarium oxysporum and F. trichothecioides in their causal relation to tuber rot and wilt of Solanum tuberosum, G. K. Link (Abs. in Science, n. ser., 43 (1916), No. 1105, p. 328).—The author states that certain strains of these two species of Fusarium have produced both tuber rot and wilt of the Irish potato. Wilt is induced by destruction of the root system and by clogging of the xylem elements in the stem, and is, in mild cases, marked by such symptoms as discoloration of the leaves, curling and rolling of the leaves, and production of aerial tubers. Under field and storage conditions, F. oxysporum is said to be probably more responsible for wilt than F. trichothecioides, while the latter species is more responsible for tuber rotting. The optimum and maximum temperatures of F. oxysporum are higher than those of F. trichothecioides. On the other hand, F. trichothecioides grows well at temperatures of 8 to 10° C. (46.4 to 50° F.), while the other species does not. F. oxysporum is considered more cosmopolitan, and it can utilize materials more readily than, but not so completely as, does F. trichothecioides.

Effect of certain species of Fusarium on the composition of the potato tuber, L. A. Hawkins (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 5, pp. 183-196).—A report is given of an investigation made to determine the effect of F. oxysporum and F. radicola on the sucrose, reducing sugar, starch, pentosan, galactan, and crude fiber content of the potato.

It was found that these fungi reduced the content of sugar, both sucrose and reducing sugar, pentosans, galactans, and dry matter. The starch and methyl pentosans were apparently not affected appreciably and the crude fiber content was not reduced. It was found that these two species of fungi secrete sucrose, maltase, xylanase, and diastase, the last-mentioned enzym apparently being incapable of acting on the ungelatinized potato starch.

Late blight of potato, G. P. DARNELL-SMITH and E. MACKINNON (Agr. Gaz. N. S. Wales, 26 (1915), No. 8, pp. 673-678, pls. 2).—Late blight (Phytophthora infestans), which became serious in New South Wales in 1909 and widespread in 1910, is said to have been considerably decreased by the dry conditions prevalent in Australia for some years past. The development of the fungus and the progress of the disease are described.

Experimental culture work is said to have shown that the fungus thrives best at 60 to 70° F., no conidia forming at temperatures above 77°, and no further growth of mycelium taking place above 88°. The conidia germinate

readily between 50 and 77°, infecting either the leaves or the tubers. Experiments are said to have shown that the loss through tuber infection is decreased if the digging is postponed for a week or more after the dying of the tops, except in very wet weather and on low, heavy soil, which conditions require early digging. Infected tubers, though capable of spreading the disease, show little or no change, the wet rots sometimes observed being due to the entrance of other organisms.

Control measures include the use of blight-free seed, complete removal of material from the previous crop, rotation, spraying (which is regarded as protective only), and the use of resistant stock. The variety New Era is said to have yielded excellent results since its appearance several years ago.

Biochemical studies on potato leaf roll disease.—V, The amylase of tubers from plants showing leaf roll, G. Doby and J. Bodnár (*Ztschr. Pflanzenkrank.*, 25 (1915), No. 1, pp. 4-16).—The work previously reported on by one of the authors (E. S. R., 28, p. 150) has been extended to a study of the amylase of tubers.

It is thought that the amylase of potatoes is present partly as zymogen, which passes over continually into the active state. The activity in freshly expressed sap showed no relation to the variety or origin of the potatoes tested. In general, sound tubers possess more zymogen than diseased ones.

These studies are not considered as having yet demonstrated a basal chemical criterion for the presence of leaf roll, or as having decided whether the chemical or biochemical changes observed in diseased tubers are the cause or the effect of the disease, or how far the optimum and the activities of amylase differ in sound and in diseased tubers.

Rice smut, A. A. L. Rutgers (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 11 (1914), pp. 7, figs. 2).—A description, with bibliography, is given of the grain smut of rice and of the causal fungus (Tilletia horrida), which is considered identical with T. corona.

A new brown spot disease of the leaf of Glycine hispida caused by Septoria glycines n. sp., T. Hemmi (Trans. Sapporo Nat. Hist. Soc., 6 (1915), No. 1, pp. 12-17).—The author describes a disease of G. hispida characterized by enlarging spots appearing on both surfaces of young leaves, which become discolored and fall, the disease working toward the top of the plants and often ruining the entire crop. The disease, which is due to a fungus described as S. glycines n. sp., spreads most rapidly in damp, warm weather and in places which are incompletely drained. In a dry season or place the disease is checked, so that the upper leaves are usually not attacked, but, if the favorable conditions set up, the disease spreads again actively.

The newly described fungus is compared as regards important characters with *S. sojina*, which is said to be the only species previously noted as parasitic on the leaves of soy bean.

Injuries and diseases of tobacco in Dalmatia and Galicia in 1911, 1912, and 1913, PREISSECKER (Fachl. Mitt. Österr. Tabakregie, 15 (1915), No. 1-3, pp. 59-64, fig. 1).—In two sections dealing separately with Dalmatia and Galicia as regards the causation, during this period, of losses to the tobacco interests, notes condensed from official reports are given on plant and animal pests, injuries due to weather, abnormalities of physiological or unknown causation, and diseases caused by fungi in various localities.

The endoconidia of Thielavia basicola, W. B. BRIERLEY (Ann. Bot. [London], 29 (1915), No. 116, pp. 483-493, pl. 1, fig. 1).—The author gives an account of his study of the conidial characters and behavior in T. basicola which are thought to be typical of those in all fungi producing endoconidia.

The first conidium differentiates an inner wall and a sheath which ruptures near its apex, freeing the conidium. Each of the later conidia grow and push out through the empty sheath of the first, being freed from the next below by the splitting of the basal wall which is formed between the two cells by the ingrowth of a basal ring which finally closes in the center.

A bibliography is appended.

Watermelon stem-end rot, F. C. MEIER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 4, pp. 149-152, pl. 1).—A preliminary report is given of investigations made to determine the cause of a decay of watermelons that has been frequently noted in shipments of those fruits. Material was secured from a shipment received in this city in July, 1915, and an examination showed that more or less injury had occurred in a very uniform manner. In the early stages the presence of decay was indicated by a watery discoloration of the rind in an area closely surrounding and apparently extending from the stem. From this all stages of decay were noted until half or more of the melon was involved. In the later stages the rind portion becomes soft and wrinkled and the flesh below is slimy and blackened.

From the material secured a fungus belonging to the genus Diplodia was isolated and inoculation experiments produced typical decay. The specific identity of the fungus has not been determined but inoculations made from a culture of *D. tubericola* produced a decay that took the same course as that described above. Species of Diplodia are known to attack a number of economic plants, and the relation of some of these to the watermelon, it is thought, might possibly show whether a species found on one host would grow equally well upon another.

Brown rot of fruit, D. M. CAYLEY (Gard. Chron., 3. ser., 58 (1915), No. 1505, pp. 269, 270, figs. 2).—It is stated that the wet weather of 1915 was probably the cause of the prevalence of Sclerotinia (Monilia) fructigena, causing brown rot of apple and pear. This form is discussed in connection with the closely related forms S. cinerea on stone fruits and S. laxa on apricots. The mycelium of S. fructigena is said to persist in the twigs, branches, spurs, and mummied fruits during the winter and to produce conidia by the time the apple and pear blossoms open. It is said that the fungus may be spread by contact of injured with sound fruits in handling, as the fungus is a wound parasite developing rapidly from very minute injuries.

A Bordeaux spray in early spring before the blossoms open is recommended. Affected parts should be removed and burned during the winter, and rotten apples should be carefully removed in summer.

Experiments for control of apple scab, H. S. Jackson and J. R. Winston (*Oregon Sta., Bien. Rpt. Hood River Sta., 1913-14, pp. 6-18, figs.* 7).—Results are given of experiments conducted in the Hood River Valley for the control of apple scab, in which lime-sulphur, atomic sulphur, soluble sulphur, and Bordeaux mixture were used separately or in combination with other materials.

As a result of one season's work, the most important application for the prevention of scab proved to be the delayed dormant spray of lime-sulphur and Black Leaf 40. Lime-sulphur was found the most efficient preventive of any one mixture used. Severe fruit injury was often found to follow summer application of lime-sulphur when made just previous to extremely hot weather. It is said that neither atomic nor soluble sulphur can be recommended as a remedy for scab when used in all applications, but good results followed the application of atomic sulphur in the calyx and subsequent applications where lime-sulphur had been used in the first application. No appreciable fruit or foliage injury was observed where this method was followed.

The use of lime-sulphur as a summer spray for apple scab, C. C. VINCENT (Idaho Sta. Bul. 85 (1916), pp. 16, figs. 5).—The results are given of three years' experiments in the use of lime-sulphur as a summer spray for apple scab. The experiments were carried out on the college orchard to ascertain the value of lime-sulphur as a summer spray for scab and to determine the number of applications needed to hold the disease in check. As a result of the work, it is claimed that lime-sulphur is an effective remedy for the control of apple scab, good results being secured during wet as well as dry seasons. The cost of three applications was 8.1 cts. per tree.

In the course of the investigation it was found that different varieties varied in resistance to the disease. Grimes Golden is said to be quite resistant, and one application made at the time the buds were showing pink reduced the fungus attack to a negligible quantity. On the other hand, Wagener, Rome, and Jonathan were subject to attack and neither one nor two applications were sufficient to check the disease completely.

In addition to spraying, the author recommends pruning, cultivation, and fertilization.

The common diseases of the pear, G. W. Martin (New Jersey Stas. Circ. 52 (1915), pp. 3-12, figs. 6).—The author describes the more common diseases of the pear and gives suggestions for their control. A spray calendar is given, in which time of application, fungicide or insecticide, and the principal causes of injury are indicated.

Apricot disease in the Rhone Valley, P. CHIFFLOT and MASONNAT (Compt. Rend. Acad. Agr. France, 1 (1915), No. 15, pp. 473-477).—The report of this outbreak has already been noted (E. S. R., 35, p. 50). Monilia cinerea and M. laxa have both been claimed to cause the disease.

Brown rot of prunes and cherries in the Pacific Northwest, C. Brooks and D. F. Fisher (U. S. Dept. Agr. Bul. 368 (1916), pp. 10, pls. 3).—The authors report upon an investigation of blossom infection and fruit rot of prunes and cherries, both of which diseases are said to have become quite destructive in parts of Oregon and Washington. The investigation indicates that the trouble is due to Sclerotinia cinerea, and spraying experiments have shown the practicability of materially reducing loss from this fungus. The blossom blight was found to be an important factor in the poor set of prune fruit in 1915, and the occurrence of the brown rot on the fruit destroyed a large amount in transit and storage.

As a result of the work with prunes, it was found that both self-boiled lime sulphur and Bordeaux mixture, when properly applied, give satisfactory control. Four applications are recommended, the first just before the blossoms open, the second after the petals have fallen, the third three or four weeks later, with a fourth about four weeks before harvesting.

Blossom infection and fruit rot of cherries due to the same cause have been investigated, and while work with cherries has not been carried out so fully as with prunes, it is thought that a treatment similar to that given for prunes would satisfactorily control the diseases.

Perocid for Peronospora on grapevines, F. Gvozdenovic (Staz. Sper. Agr. Ital., 48 (1915), No. 3, pp. 153-174).—Perocid, three forms of which are prepared as chemical by-products, is said to have shown a considerable degree of efficiency for the control of grape downy mildew.

Citrus bark rot, G. H. Zerbst (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 2, pp. 95-97).—It is stated that since 1911 citrus culture has suffered severely from a bark rot occurring over practically the entire province of

Batangas. The mandarin (C. nobilis) appears to be extremely sensitive, the calamondin (C. mitis) being less severely injured, and the sweet orange (C. aurantium) and the pomelo (C. decumana) being seldom affected to a serious degree.

The disease and its results are described. It is supposed to be produced by unfavorable soil and culture conditions, one of the main factors being the packing of the soil, which prevents aeration and drainage. Irregularity of water supply appears to be another factor. Recommendations include proper plowing, varying in depth each year, planting in the rainy season to cover crops, which should be cut and left as a mulch during the dry season, removal of diseased spots, and covering the wounds with lead paint.

Some abnormalities of the coconut palm, T. Petch (Ann. Roy. Bot. Gard. Peradeniya, 6 (1915), No. 1, pp. 21–30).—The author gives an account of abnormalities which he has noted during the last few years, including yellow coconuts, double coconuts, prolification, and hypertrophy of the perianth.

The effect of lightning on coconut palms, T. Petch (Ann. Roy. Bot. Gard. Peradeniya, 6 (1915), No. 1, pp. 31-42).—The author gives collected accounts and his own observations of injuries to coconut palms by lightning in tropical and subtropical regions. The visible effects discussed are combustion of the crown, mechanical injury, and exudation of the gum, often with little or no indication of mechanical injury. The last is thought to be sometimes connected in some way with the heat generated by the electrical discharge.

Black canker of chestnut, L. Petri (Alpe [Italy], 2. ser., 2 (1915), Nos. 3, pp. 94-99, pl. 1; 5, pp. 188-196, figs. 3).—Discussing the findings and views of others regarding the factors which produce or favor black canker of chestnut, the author describes the phenomena observable in the origin and development of the abnormal conditions associated with the presence of several fungi. He distinguishes between the rapid and quickly fatal attack usual to Coryneum and the progress and behavior of the other fungi which commonly precede it as regards the original attack and in some cases possibly furnish the conditions for its rapidly destructive phase. It is stated that frost injuries apparently favor Coryneum attack, which, in this case, may be of limited extent.

From a study of the questions whether black rot of the roots precedes or follows the infection of the branches and stem and whether Coryneum is able to attack directly the roots and base of the trunk, the author has concluded that, in case of plants just beginning to show disease, the base of the trunk and contiguous portions of the larger roots may be found to show the alterations associated with black rot before Coryneum can be demonstrated in the upper portions. The infection of the base of the stem by Coryneum may be noted in nursery stock or in chestnuts used as replants where older plants have died with black rot. The initially basal attack by Coryneum appears to be limited by the age of the plant. It is said that it may be difficult in an advanced stage of the disease to establish the order of precedence of the two infections, that of Coryneum proceeding from above downward and that of other fungi proceeding upward.

The influence of the tannin content of the host plant on Endothia parasitica and related species, M. T. Cook and G. W. Wilson (Bot. Gaz., 60 (1915), No. 5, pp. 346-361).—This is a more extended report on investigations the main results of which have been noted from another source (E. S. R., 32, p. 646).

The influence of ether on the growth of Endothia, M. T. Cook and G. W. Wilson (Bot. Gaz., 60 (1915), No. 5, pp. 412, 413).—The authors, giving results of some studies in connection with those noted above, state that while small quantities of ether in liquid culture media appear to have a stimulating effect

on *E. parasitica*, the use of proportions from 0.2 per cent up retards germination, and the use of those from 0.4 per cent upward results injuriously to the growth of the fungus.

Diseases and injuries of Hevea brasiliensis in Java, A. A. L. Rutgers and K. W. Dammerman (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 10 (1914), pp. 45, pls. 12, flg. 1).—This is a somewhat systematic discussion of local insect enemies, diseases, and abnormalities of H. brasiliensis classified according to portion of the plant attacked, with references under the several sections to related literature. Parasitic fungi named in connection with diseases include, on the roots, Fomes semitostus, Hymenochate noxia, and Spharostilbe repens; on the branches, Corticium salmonicolor (C. javanicum), Thyridaria tarda, Glæosporium alborubrum, and Phyllosticta ramicola; on the trunk, Phytophthora faberi; and on the leaves, Phyllosticta heveæ and Pestalozzia palmarum. Injurious changes in the latex and prepared rubber are discussed, also such abnormalities as excrescences and fasciations.

The pseudosclerotia of Lentinus similis and L. infundibuliformis, T. Petch (Ann. Roy. Bot. Gard. Peradeniya, 6 (1915), No. 1, pp. 1-18, pl. 1).—Reviewing related contributions and describing a study of sclerotia in Lentinus found on stumps of Hevea brasiliensis, the author states that in addition to species possessing a true sclerotium, there appear to exist others whose mycelium merely binds together the earth in a large compact mass, while L. similis and L. infundibuliformis exhibit a third type in which the skeleton of the pseudosclerotium consists of the wood of the host plant. It is considered as still an open question whether these types are definitely associated with different species of Lentinus or are merely stages which may be assumed by the sclerotium in any given species.

Leaf-spot disease of lime, E. S. Salmon and H. Wormald (Gard. Chron., 3. ser., 58 (1915), No. 1500, pp. 193, 194, figs. 2).—It is stated that a leaf and shoot disease of lime or linden trees near Maidstone in Kent has been identified as Glæosporium tiliæcolum, reported on the Continent by Laubert in 1904 (E. S. R., 16, p. 988), but not previously recorded in England. The disease and the habits of the fungus are described.

Infection studies with Melampsora on Japanese willows, T. Matsumoto (Trans. Sapporo Nat. Hist. Soc., 6 (1915), No. 1, pp. 22-37, figs. 5).—Giving an account of morphological, systematic, and infection studies, regarded as being of a preliminary character, on several species of Melampsora, the author expresses his belief that a connection exists between the Melampsora on Populus spp. and the cæoma spores on Chelidonium majus, although this could not be definitely settled with the material obtained. It is thought probable that a disease of Salix caprea in Japan may be due to the rust fungus which has been designated as M. larici-capræarum.

Technical descriptions are given of the new species M. yezoensis on S. jessoensis (cæoma stage on Corydalis ambigua), M. larici-miyabeana on S. miyabeana (cæoma on Larix europæa and L. leptolepis), and M. larici-opaca on S. opaca (cæoma on L. europæa and L. leptolepis).

The recent outbreaks of white pine blister rust, P. Spaulding (Jour. Wash. Acad. Sci., 6 (1916), No. 4, pp. 102, 103).—Giving a brief account of white pine blister rust in this country, the author states that in the years 1909 to 1914 there were 11 outbreaks of the disease; that is, cases where it escaped from diseased pines and attacked currant or gooseberry. Owing to favorable weather conditions during 1915, it spread very readily and for relatively long distances. Twelve outbreaks were noted, the extent of attack varying from a few bushes to a single area of from 400 to 500 square miles. It is stated that all of the

species of currant and gooseberry tested thus far have been found to be susceptible, the widely distributed black currant (*Ribes nigrum*) being especially so.

Discussion on decay in timber (Trans. Canad. Soc. Civ. Engin., 29 (1915), pt. 1, pp. 324-365, figs. 29).—This discussion, participated in by a number of engineers, deals with the conditions, forms, and results of attacks on various woods, as in mill and other structural timbers, by fungi, more particularly by Mcrulius lacrymans, Coniophora cerebella, and Tranetes serialis, as well as other fungi not yet identified.

Among the more resistant woods heart pine stands very high, as does also wood containing tannin in relation with Merulius. Moisture which may condense following a fall in temperature greatly favors attacks in many cases. Air driven from near the surface of warm, moist earth may become saturated and give up moisture in a cooler underground space, wetting the wood instead of drying it. A water pipe may cool surrounding air to saturation and rot adjacent timbers. Certain materials absorb water at high temperatures and give it up at lower temperatures. Hygroscopic salts may form in certain situations or processes. It is thought that M. lacrymans may obtain the moisture and oxygen it requires from the wood it decomposes.

A bibliography is appended.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

A history of British mammals, G. E. H. BARRETT-HAMILTON and M. A. C. Hinton (London: Gurney & Jackson, 1915, [vol. 2], pt. 17, pp. 503-552, pls. 2, figs. 4).—A continuation of the Muridæ of the Rodentia, previously noted (E. S. R., 34, p. 57) in which descriptions of the field mouse, the Hebridean field mouse, the St. Kilda field mouse, the Fair Isle field mouse, the yellow-necked field mouse, and De Winton's field mouse of the genus Apodemus are given, and a description of the genus Micromys commenced.

Some observations on the rate of digestion in different groups of wild birds, W. E. Collinge (*Jour. Econ. Biol.*, 10 (1915), No. 3, pp. 65-68).—Experiments tabulated show that the rate of digestion differs in the rook from that in the English sparrow, and that these two birds and the starling digest the stomach contents in a period of from 4 to 4.5 hours.

A synopsis of the races of the long-tailed goat-sucker, Caprimulgus macrurus, H. C. Oberholser (*Proc. U. S. Nat. Mus.*, 48 (1915), pp. 587-599).

A review of the subspecies of the ruddy kingfisher, Entomothera coromanda, H. C. OBERHOLSER (Proc. U. S. Nat. Mus., 48 (1915), pp. 639-657).

Entomological investigations, H. F. Wilson and L. Childs (Oregon Sta., Bien. Rpt. Hood River Sta., 1913-14, pp. 40-50).—In studies made of the insects of the Hood River Valley, the codling moth was found to be the most important pest. Observations of this insect made during the period under report indicate the occurrence of a third brood. It is said that during the last two or three weeks prior to harvesting, a large number of young larvæ appeared and entered the fruit, causing considerable damage, and that the damage was serious, even in orchards where three spray applications had been previously made.

Statistical data relating to codling moth work in twelve orchards are presented in tabular form for several varieties of apple, showing the extent of damage to the fruit, with various spraying dates, strengths, and combinations of brands. Arsenate of lead in combination with blackleaf 40, lime-sulphur, and Bordeaux mixture gave very efficient results.

Observations relative to seasonal history and habits are included. The adults emerge in May and commence to oviposit as soon as the evening temperature rises to 60° F. or above, which condition prevails about June 1. The earliest

larvæ in the spring reach maturity about July 7 to 10, from which time mature larvæ and pupæ can be found until the latter part of July. By August 1 the eggs of the second generation begin to appear, and by August 10 the young larvæ are entering the fruit quite freely. Larvæ and pupæ were found in October, which, it is thought, may have been the third generation of moths, above mentioned, or possibly stragglers from the second generation. Brief reference is made to the control of the codling moth by the two forms of arsenate of lead, a report upon which has been previously noted (E. S. R., 34, p. 548). The second spray should be made at the time the eggs are hatching and the first brood of larvæ are entering the fruit, probably three or four weeks after the calyx or first spray, or about the first or second week in June. The third application, usually given to check the larvæ of the second brood, should be made about six weeks after the second, or from July 25 to August 5. Where a fourth spray is thought desirable for late-appearing larvæ, it should be applied about September 1.

Data relating to a number of minor pests follow. Those thus mentioned are the brown mite, which feeds primarily on clover, alfalfa, and peas, but also occurs on fruit trees and in some instances causes considerable injury; the climbing or variegated cutworm which bores into the fruit; the fruit-tree leaf-roller, which, though present in the Hood River Valley for a number of years, has only been a source of damage during the past two or three years; the brown apple aphis which has been the source of considerable loss through its injury to the fruit; the woolly apple aphis and the green apple aphis; the pear slug; the San José scale and oyster shell scale; the peach and prune twig miner; and the apple leaf miner.

Proceedings of the Entomological Society of British Columbia, 1915 (*Proc. Ent. Soc. Brit. Columbia, n. scr., No.* 7 (1915), pp. 48).—The first part (pp. 5–21) of this report presents the proceedings of the second midsummer meeting of 1914, the second part (pp. 22–45) those of 1915, in continuation of the report previously noted (E. S. R., 34, p. 651).

The following are the more important papers presented: Insect Notes from the Okanogan in 1914, by M. Ruhman (pp. 7-11); The Control of Incipient Infestation of Codling Moth in a New District, by W. H. Lyne (pp. 11-13); Sprays of Up-To-Date Interest, by L. L. Palmer (pp. 14-16); The Tarnished Plant Bug (Lygus pratensis), by R. C. Treherne (pp. 16-18); The Part Played by Insects in the Spread of Plant Diseases, by J. W. Eastham (pp. 18-21); Insect Pests in Greenhouses, by G. E. Wilkerson (pp. 25-30); Notes on Some Insects of the Lower Fraser Valley, by F. H. Getchell (pp. 30-33); Comments on Some Peculiarities in Connection with the Life History of the Codling Moth on the Pacific Coast, by W. H. Lyne (pp. 33-35); Shade Tree and Ornamental Insects of British Columbia, by R. C. Treherne (pp. 35-41); The Outbreak of Locusts of 1914, by T. Wilson (pp. 41-43); Notes on Birds Likely to be of Service in the Destruction of Grasshoppers in the Nicola Valley, by L. E. Taylor (pp. 43-45); and The Kansas Remedy for the Control of Locusts, by A. Gibson (p. 45).

[Economic entomology] (Ztschr. Angew. Ent., 2 (1915), No. 1, pp. 264, figs. 119).—The several papers here presented deal with The Potato Fleabeetle (Psylliodes affinis), of which the morphology and biology of the immature stages are considered by F. Tölg (pp. 1-9) and the morphology and bionomics of the adult, by F. Heikertinger (pp. 10-28); Flacherie of the Mediterranean Flour Moth (Ephestia kühnicila) and the Causative Agent, Bacillus thuringicasis n. sp., by E. Berliner (pp. 29-56); Biology of the Tachinids Parasetigena segregata and Panzeria rudis, by H. Prell (pp. 57-148); Artificial Infestation of the Vine Caterpillars (Cochylis ambiguella and Polychrosis botrana) by

Parasitic Insects, by K. H. C. Jordan (pp. 149–157); Morphological and Systematic Investigations of the Red Spider (*Tetranychus dufour*), by I. Trägårdh (pp. 158–163); and Notes on the Outbreaks of the Kieferneule (*Panolis piniperda*) in the Dresden Forest Reserve, by Neumeister (pp. 164–167).

The distribution of California insects, I, E. O. Essig (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 3, pp. 113–120, figs. 6).—The author considers the distribution of six of the more important insects occurring in California, and presents maps which show the occurrence of each.

Observations on insect pests in Grenada, H. A. Ballou (Bul. Ent. Research, 6 (1915), No. 2, pp. 173-181).—The notes here presented relate to the cacao thrips (Heliothrips rubrocinctus), the cacao beetle (Stirastoma depressum), the acrobat ant (Cremastogaster sp.), and the control of scale insects by natural enemies.

The insects of central Europe, especially Germany, edited by C. Schröder (Die Insekten Mitteleuropas insbesondere Deutschlands. Stuttgart: Franckh'sche Verlagshandlung, 1914, vols. 2, pp. VIII+256, pls. 5, figs. 124; 3, pp. VIII+213, pls. 8, figs. 133).—In the second volume of this work, the first of which is not at hand, the Formicidæ are dealt with by H. Stitz (pp. 1-111) and the Ichneumonidæ, Braconidæ, Chalcididæ, etc., by O. Schmiedeknecht (pp. 113-256); and in the third the Cynipidæ by J. J. Kieffer (pp. 1-94) and the Tenthredinidæ, Cephidæ, Siricidæ, and Oryssidæ by E. Enslin (pp. 95-213). An extensive bibliography and an index to the genera and species accompany each paper. Several colored plates are included.

Manufacturing tests of cotton fumigated with hydrocyanic-acid gas, W. S. Dean (U. S. Dept. Agr. Bul. 366 (1916), pp. 12).—Spinning and chemical laboratory tests reported indicate that fumigation of cotton with hydrocyanic-acid gas does not affect, to any material extent, the percentages of waste, spinning qualities, tensile strength, bleaching, dyeing, or mercerizing properties of the cotton.

Contribution to the knowledge of olive insects of Eritrea and of South Africa, F. Silvestri (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 9 (1914–15), pp. 240–334, figs. 78; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 5, pp. 765–768).—A detailed account of observations of insect enemies of Olea chrysophylla and O. verrucosa made during the course of excursions in quest of parasites of the olive fly (Dacus olea). Systematic descriptions of many species new to science are accompanied by biological notes.

Forest insects of Sweden, I. Trägårdh (Sveriges Skogsinsekter. Stockholm: Hugo Gebers, pp. VIII+279, pls. 16, figs. 136; rev. in Canad. Ent., 47 (1915), No. 6, pp. 199, 200).—Following preliminary chapters on the characters and organization of insects, their development, and general methods of control, the author deals with the different orders, commencing with the Coleoptera, describing those families and their members that are injurious to forests or useful as parasitic or predacious enemies of forest insects. A special chapter is devoted to gall-making insects and Eriophyes and another to control measures. The work concludes with a table giving keys to the various insects according to the trees and parts of the trees they attack.

Descriptions of a new genus and species of the discodrilid worms, M. C. Hall (Proc. U. S. Nat. Mus., 48 (1915), pp. 187-193, figs. 3).—Ceratodrilus thysanosomus collected on crayfish in the streams of Great Basin, Salt Lake City, Utah, is described as representing a new genus and species.

An anatomical note on the genus Chordeiles, A. Wetmore (*Proc. Biol. Soc. Wash.*, 28 (1915), pp. 175, 176, fig. 1).

White ants in Japan, M. Yano (Extracts from Bul. Forest Expt. Sta., Tokyo, 1915, pp. 134-142, pls. 3).—The present paper describes three species of termites which occur in the main island, Shikoku, and Kiushu, namely, Leucotermes (Reticulitermes) speratus, Coptotermes formosanus, and Calotermes (Glyptotermes) satsumensis, including their life history, natural enemies, distribution, and the damage which they cause.

A new Trichodectes from the goat, V. L. Kellogg and S. Nakayama (*Psychc*, 22 (1915), No. 2, pp. 33-35, fig. 1).—The name *Trichodectes hermsi* is given to a species taken from a badly infested young merino goat near Inverness, Marin County, Cal.

Dendrotettix quercus, A. N. CAUDELL (*Psyche*, 22 (1915), No. 2, pp. 52-54).—Considerable damage was done by this species at New Lisbon, N. J., during the season of 1914.

The control of locusts in Italy, A. Lunardoni (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 4, pp. 522-532, pls. 2).—A summary of control work in Italy.

The question of the bacterial method of controlling locusts, A. V. Gratchov (Zhur. Mikrobiol., No. 1-2 (1914), p. 175; abs. in Rev. Appl. Ent., Ser. A, 3 (1915), No. 11, pp. 699, 700).—The author suggests the passing of the bacillus (Coccobacillus acridiorum) directly from dead insects of one series into those of another without any intermediate cultivation on agar-agar, thus eliminating the danger of losing the virus.

The biological method for the destruction of locusts, F. D'HERELLE (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 17, pp. 503-505; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 1, pp. 14, 15).—A further report of work with Coccobacillus acridiorum (E. S. R., 31, p. 752), which was carried on in Tunis.

A test of Coccobacillus acridiorum d'Herelle on locusts in the Philippines, M. A. Barber and C. R. Jones (Philippine Jour. Sci., Sect. B, 10 (1915), No. 2, pp. 163-176).—Experiments conducted in the Philippines with Œdaleus nigro-Jasciatus and Locusta migratoroides in which cultures of C. acridiorum from the Pasteur Institute were used gave negative results. Reports received from consuls in Argentina, Colombia, and Algeria in response to a request for information regarding the results obtained from the use of C. acridiorum in those countries are appended. The information given seems to indicate that thus far the use of this organism has not been practical.

Two new Thysanoptera from West Africa, with a note on the synonymy of the Phlæothripidæ, J. D. Hoop (Psyche, 23 (1916), No. 1, pp. 6-12, pl. 1).

A new vine thrips from Cyprus, R. S. BAGNALL (Bul. Ent. Research, 6 (1915), No. 2, pp. 199, 200).—A thrips which is injurious to vines in Cyprus is described as Cryptothrips brevicollis n. sp.

The cabbage harlequin bug or calico bug (Murgantia histrionica), W. A. THOMAS (South Carolina Sta. Circ. 28 (1915), pp. 4, fig. 1).—A brief account with remedial measures.

The immature stages of Tropidosteptes cardinalis, M. D. Leonard (*Psyche*, 23 (1916), No. 1, pp. 1-3, pl. 1).—This capsid was the source of some injury to the leaves of ash at Ithaca, N. Y.

Synoptical keys to the genera of the North American Miridæ, E. P. VAN DUZEE (Univ. Cal. Pubs., Ent., 1 (1916), No. 3, pp. 199-216).—The keys here given cover all but eight of the genera of the hemipterous family Miridæ thus far recorded from America north of Mexico.

The immature stages of two Hemiptera, Empoasca obtusa and Lopidea robiniæ, M. D. Leonard (*Ent. News*, 27 (1916), No. 2, pp. 49-54, pls. 2).—Technical descriptions are given of the several stages of these insects.

A psyllid gall on Juneus (Livia maculipennis), Edith M. Patch (Psyche, 23 (1916), No. 1, pp. 21, 22, pl. 1).—The author records the occurrence of L. maculipennis on Juneus at Magnolia Village, Mass.

A synopsis of the aphid tribe Pterocommini, H. F. Wilson (Ann. Ent. Soc. Amer., 8 (1915), No. 4, pp. 347-358, figs. 13).—Ten species of this tribe have been described, of which three have been recorded from Europe and five from America. All the known species commonly feed on willows and poplars, and one species is recorded as also being found on maple.

The pea aphis, A. Mordvilko (*Trudy Bûro Ent.* [*Petrograd*], 8 (1915), *No.* 3, 2. rev. and enl. ed., pp. 54, pls. 2, figs. 4; abs. in Rev. Appl. Ent., Ser. A, 8 (1915), *No.* 11, pp. 702-704).—The second revised and enlarged edition of this paper. The synonymy and a bibliography are appended.

Some intermediates in the Aphididæ, A. C. BAKER and W. F. TURNER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 1, pp. 10-14).

A new genus and species of Aleyrodidæ from British Guiana, A. L. QUAINTANCE and A. C. Baker (Ann. Ent. Soc. Amer., 8 (1915), No. 4, pp. 369-371, figs. 18).—Eudialeurodicus bodkini n. g. and n. sp., reared from leaves of Erythrina glauca at Berbice, is described.

The European fir trunk bark louse (Chermes [Dreyfusia] piceæ) apparently long established in the United States, J. Kotinsky (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 1, pp. 14-16).—Specimens of balsam fir bark rather heavily infested with this bark louse are said to have been received from Mt. Monadnock, N. H. It is stated that the infestation has been spreading during the past three years and that a considerable number of trees have died during that time.

Reports on scale insects, J. H. Comstock (New York Cornell Sta. Bul. 372 (1916), pp. 425–603, pls. 26, figs. 15).—This bulletin brings together the author's writings on the Coccidæ or scale insects, the first of which (pp. 425–500), entitled Reports on Scale Insects, appeared in the report of the U. S. Commissioner of Agriculture for 1880; the second (pp. 501–506), Report of the Entomologist, United States Department of Agriculture, appeared in the report of the U. S. Commissioner of Agriculture for the years 1881 and 1882; and the third (pp. 507–603), Report of the Department of Entomology, is from the second report of the Cornell Station, 1883. The pagination and the figure numbers and their sequence in the original reports have been retained.

The Coccide of New Jersey greenhouses, H. B. Weiss (*Psyche*, 23 (1916), No. 1, pp. 22-24).—The author lists 32 species representing 17 genera found infesting various plants in New Jersey greenhouses.

White wax coccid (Ericerus pela), M. Yano (Extracts from Bul. Forest Expt. Sta., Tokyo, 1915, pp. 143-150, pls. 2).—The male larvæ of this coccid secrete a white wax which is collected and known in commerce as insect wax or Chinese wax. The author gives a description of the several stages of this coccid and an account of its life history, host plants, and natural enemies, namely, Brachytarsus niveovariegatus, Dasyneura sp., a new chalcidid, Chilocorus similis, and C. tristis.

The oyster-shell scale and the scurfy scale, A. L. QUAINTANCE and E. R. SASSCER (U. S. Dept. Agr., Farmers' Bul. 723 (1916), pp. 14, figs. 3).—A revision of Bureau of Entomology Circular 121, previously noted (E. S. R., 23, p. 156).

The pink corn worm: An insect destructive to corn in the crib, F. H. CHITTENDEN (U. S. Dept. Agr. Bul. 363 (1916), pp. 20, pls. 4, figs. 7).—The larva of a small moth (Batrachedra rileyi). known as the pink corn worm, has been found in cornfields of the southern United States for nearly three-fourths of

a century, but not until 1914 was it recognized as a pest. During November and December of that year numerous complaints were made of damage to corn in cribs, especially in Mississippi. The attack begins in the field and continues after the corn has been stored. When the stored ears are husked they show injury by accumulations of webbing and frass or excrementitious matter.

"The eggs are deposited in the field where the tips of the corn ears are more or less open, due to the attack of the corn ear worm. After the latter has departed the pink corn worm continues the injury and by its work makes it easy for other insects and water to enter the ears, which eventually are ruined. From the cob or between the rows of grains the worm penetrates the kernels at the tip or point of attachment, works into the embryo or 'germ,' which it destroys, then outward to the crown.

"Unlike the Angoumois grain moth and the rice weevil, which are usually to be found working in the same fields and frequently in the same ears, this 'worm' does not confine itself to the kernel, but attacks kernel, husk, and cob alike. Also, unlike most other grain pests, it appears to be confined among cereals to corn and sorghum, although it attacks, but does not seriously injure, cotton bolls which are more or less open, and some other plants.

"While thus far it has proved most injurious in Mississippi, it ranges from South Carolina westward to central Texas, southward to tropical Texas, and northward to Arkansas and Tennessee. During the years 1914-15 the pink corn worm was reported to have occasioned very considerable injury, and much alarm was felt because of its abundance in the regions mentioned. Naturally it can not be foretold when, if ever, such an outbreak will recur.

"As a preventive of injury, corn should be left in the field no longer than is absolutely necessary for drying it; the husks should then be removed as soon as possible, the poorest of the infested ears destroyed promptly or fed to swine or poultry, and the best ears fumigated with carbon bisulphid according to the directions given. The bins or cribs should be kept scrupulously clean, and should be fumigated before new material is stored in them. Cooperation among corn growers of as large a territory as possible where the species occurs should be secured that future losses may be prevented."

A bibliography of ten titles is appended.

Notes on large scale experiments against the pink bollworm in cotton seed, G. Storex (Agr. Jour. Egypt, 4 (1914), No. 2, pp. 115-124, pls. 2).—These notes describe and report the results of experiments on the hot-air treatment and fumigation treatment of cotton seed for the pink bollworm (Gelechia gossypiella).

A note on the recent attack of Brassolis sophoræ, L. D. CLEARE, Jr. (Jour. Bd. Agr. Brit. Guiana, 8 (1915), No. 3, pp. 86, 87).—This lepidopteran was the source of considerable injury to coconut palms at Georgetown during 1914, approximately 5 per cent of the palms having succumbed to its attack.

Studies on the vine moths, M. Topi (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. et Nat., 5. ser., 24 (1915), I, No. 5, pp. 464-468, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 6, pp. 890-892).—This paper reports further studies (E. S. R., 34, p. 63) made of the bionomics and of control measures for Cochylis ambiguella and Polychrosis botrana.

Contribution to the knowledge of Carpocapsa pomonella, G. Sciarra (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 10 (1915), pp. 33-50, fig. 1; abs. in Rev. Appl. Ent., Ser. A. 4 (1916), No. 1, pp. 16, 17).—This reports studies of the bionomics of the codling moth, its economic importance, etc.

Observations of the biology of Anarsia lineatella, injurious to the almond, R. Sarra (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 10 (1915), pp. 51-65, figs. 3; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 1, pp. 17, 18).—The peach twig moth is said to have two generations in Italy, the first appearing late in May and in June and July, and the second early in September and in October. In addition to almonds it attacks prunes, plums, apricots, and peaches, and has also been recorded on apples.

The fir bud moth (Argyresthia illuminatella), I. Trägårdh (Skogen, 2 (1915), No. 7, pp. 188-191, figs. 2; abs. in Rev. Appl. Ent., Ser. A, 3 (1915), No. 11, p. 697).—A. illuminatella, hitherto only recorded from Germany where it sometimes injures fir plantations, is said to be common in Sweden, although it is now recorded as a pest in that country for the first time. The larva attacks the young buds and hibernates therein, pupation taking place in May of the following year and the moths appearing in the latter half of June.

A new coconut palm pest in Java, P. E. Keuchenius (Centbl. Bakt. [etc.], 2. Abt., 43 (1915), No. 19-24, pp. 602-609, pl. 1).—An account of the pyralid Mclissoblaptes rufovenalis and its injury to the coconut palm.

The classification of lepidopterous larvæ, S. B. Fracker (*Ill. Biol. Monographs*, 2 (1915), No. 1, pp. 169, pls. 10).—The first part of this work (pp. 11-40) relates to the homology of the setae, and the second or main part (pp. 41-141) consists of a systematic outline of families and genera. A glossary and bibliography are included.

Résumé of work in Peru on Phlebotomus verrucarum and its agency in the transmission of verruga, C. H. T. Townsend (An. Zool. Aplicada, 1 (1914), No. 1, pp. 44-64, figs. 24).—This is a summary of the author's investigations of verruga, of which accounts have been noted from other sources (E. S. R., 34, p. 355).

Behavior of Anopheles albimanus and A. tarsimaculata, J. Zetek (Ann. Ent. Soc. Amer., 8 (1915), No. 3, pp. 221-271, figs. 6).—This paper is largely a report of definitely observed and demonstrated flights of A. albimanus and its racial variety tarsimaculata.

"The life cycle of A. tarsimaculata was found to be from seven to nine days. Direct observations from boats and on land showed a distinct flight of hordes of A. tarsimaculata and A. taniorhynchus toward Gatun, beginning at dusk, and lasting about 30 to 45 minutes. There was a return flight from Gatun to the breeding place beginning at early dawn and lasting until objects could be easily discerned, about 30 minutes duration. This return flight takes place higher in the air and is characterized by haste."

The mosquito and its relation to public health work in the Tropics and subtropics, L. E. Cooling (Jour. Roy. Sanit. Inst., 36 (1915), No. 10, pp. 424-434, pls. 2).—This paper includes a table which shows the difference between the more important species of mosquitoes of Brisbane, namely, Stegomyia fasciata, Culex fatigans, Culicelsa vigilax, and Nyssorhynchus annulipes, and their various stages.

The Simulidæ of northern Chile, F. Knab (An. Zool. Aplicada, 1 (1914), No. 1. pp. 17-22, fig. 1).—Three species are described of which one, Simulium tenuipes, is new to science.

The rôle played by the insects of the dipterous family Phoridæ in relation to the spread of bacterial infections.—Experiments on Aphiochæta ferruginea with the cholera vibrio, D. N. Roberg (Philippine Jour. Sci., Sect. B, 10 (1915), No. 5, pp. 309-336).—The experiments here reported indicate that A. ferruginea may serve as a possible porter or carrier of Asiatic cholera.

Notes and descriptions of Pipunculidæ, N. Banks (*Psyche*, 22 (1915), No. 5, pp. 166-170, pl. 1).—Four species are described as new and 18 species noted as found in Virginia, making a total of 27 pipunculids recorded from that State.

Report on some parasitic and predacious Diptera from northeastern New Mexico, W. R. Walton (Proc. U. S. Nat. Mus., 48 (1915), pp. 171-186, pls. 2).— This annotated list of species collected in connection with an investigation of the New Mexico range caterpillar (Hemileuca olivia) includes descriptions of several species new to science, namely, Rhynchiodexia flavotessellata n. sp., at Eagle Tail Mountain; Zelia wildermuthii n. sp., at Koehler; Websteriana costalis n. g.; and Neodichocera tridens n. g. and n. sp., at Koehler, N. Mex.

Nonintentional dispersal of muscoid species by man, with particular reference to tachinid species, C. H. T. Townsend (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 1, pp. 18-20).

New species of Tachinidæ from New England, H. E. SMITH (Psyche, 22 (1915), No. 3, pp. 98-102).

[Control of the house fly], R. Hulbert (North Dakota Sta. Spec. Bul., 4 (1916), No. 3, pp. 65-72, figs. 2).—A summary of measures for the control of the house fly.

Does the house fly hibernate as a pupa? H. Lyon (*Psyche*, 22 (1915), *No.* 4, pp. 140, 141).—Experiments were conducted at Harvard University during the winter of 1914–15 to determine if it is possible for the house fly to overwinter in the pupal stage.

"The results of these experiments, which represented quite natural conditions and the especially favorable conditions of the basement of the building, seem to indicate that the house fly can not easily overwinter as a pupa, although it can emerge until the middle of winter. It would seem, therefore, that the appearance of seemingly freshly emerged adults in any considerable numbers during late winter and early spring should be accounted for in some other way."

Will the Mediterranean fruit fly (Ceratitis capitata) develop in Italian lemons? G. Martelli (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 9 (1914), pp. 161-164).—The author fails to find evidence that C. capitata will develop in lemons.

The Mediterranean fruit fly (Ceratitis capitata) in the environs of Paris, P. Lesne (Compt. Rend. Acad. Agr. France, 1 (1915), No. 16, pp. 495-497; abs. in Rev. Appl. Ent., Ser. A, 3 (1915), No. 11, p. 694).—This fruit fly, first recorded as a source of injury to apricots in the Paris district in 1900 and the source of serious injury to peaches in 1906, was found in October, 1914, to be the source of injury to pears.

Preliminary note on a dipterous enemy of the peach, Legendre (Bul. Écon. Gouvt. Gén. Madagascar, 14 (1914), III-IV, No. 3-4, p. 242; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 6, pp. 893, 894).—The author records the occurrence of the Mediterranean fruit fly in Madagascar.

On the Ethiopian fruit flies of the genus Dacus, M. Bezzi (*Bul. Ent. Research*, 6 (1915), No. 2, pp. 85-101, figs. 14).—Twenty species are here considered, of which six are described as new.

New American species of Asteia and Sigalsoësa, J. M. Aldrich (Psyche, 22 (1915), No. 3, pp. 94-98, pls. 2, figs. 2).

The host of Zelia vertebrata, J. A. Hyslop (Psyche, 23 (1916), No. 1. pp. 24, 25).—The author records the rearing of this dipteran from Meracantha contracta.

Notes on the cat flea (Ctenocephalus felis), H. Lyon (*Psyche*, 22 (1915), No. 4, pp. 124-132, pl. 1, figs. 4).—The notes here presented relate to the infestation of 139 cats, the seasonal abundance of the cat flea, the method of raising fleas, observations on the anatomy of the larva, etc.

The rose chafer: A destructive garden and vineyard pest, F. H. CHITTENDEN and A. L. QUAINTANCE (U. S. Dept. Agr., Farmers' Bul. 721 (1916), pp. 8, figs. 4).—This popular account of the rose chafer and methods of control is an enlarged revision of Circular 11 of the Bureau of Entomology.

The cherry leaf beetle, a periodically important enemy of cherries. R. A. Cushman and D. Isely (U. S. Dept. Agr. Bul. 352 (1916), pp. 28, pls. 5, figs. 9).—The present studies with Galcrucella cavicollis were in large part conducted at North East, Pa.; observations made at the New York Cornell Station by Herrick and Matheson have been previously noted (E. S. R., 34, p. 756).

The authors find the pin, fire, or bird cherry (*Prunus pennsylvanica*) to be the natural food plant of this insect. The wild black cherry (*P. serotina*) and chokecherry (*P. virginiana*) are entirely immune from attack, even by the beetles. Among the cultivated fruits only sour cherry and peach trees are attacked, the sweet cherry and plum not being attacked at all.

The outbreak of 1915 is said to have been by far the most injurious that has ever occurred, the damage having been caused throughout two comparatively large regions, the one in the Appalachian region involving the greater part of New York, Pennsylvania, and northern West Virginia; the other in the northern part of lower Michigan, especially in the Grand Traverse region, where cherry growing is very extensive.

In the vicinity of North East, Pa., the beetle appeared on June 7, literally covering the leaves of the trees attacked, the source of the migration having been to the south of the grape belt, from cut-over forest land grown over by pin cherry, the foliage of which had been reduced by a freeze on May 27 and in part of the range by the tent caterpillar also. The beetles gradually disappeared until by the latter part of June practically all had gone, although a few scattering ones were found as late as early August.

The adult feeds almost exclusively on the underside of the leaves, eating small, irregular holes through the lower epidermis and parenchyma and sometimes through the entire leaf. To an extent it feeds also upon the fruit of the cherry, scarring and pitting it. The larvæ of all ages feed in a manner similar to the adults on the undersurface, eating through the leaf to the upper epidermis but leaving that intact. The period of economic injury of this beetle extended over 14 or 18 days after its first appearance in June.

Technical descriptions are given of its life stages. Data relating to life history studies of nearly 600 individuals, almost half of which were carried through their entire development from hatching to emergence of the adult insect, are reported upon, much of the data being presented in tabular form. The larvæ continued to hatch out as late as August 18 and were observed on pin cherry as late as September 10. The active feeding portion of the larval life in the cages varied from 10 to 20 days, the average being 12.33 days. The period spent in the ground in the cages varied from 14 to 28 days, the average being 22.36 days, and the total developmental period being from 45 to 50 days.

A small carabid beetle (*Lebia ornata*) was found to attack both pupæ and callow adults voraciously.

The control experiments conducted are briefly summarized as follows:

"Arsenate of lead must be used at a rate of not less than 5 lbs. to 50 gal. of water to be effective in protecting trees from injury by the cherry leaf beetle. A mixture to which molasses was added at the rate of 1.5 gal. to 50 gal. of the mixture was effective in killing practically all of the beetles which fed upon the

trees on which this mixture was applied. This addition of sweetening to the arsenate has the serious disadvantage of making the spray easily washed off by rains. Arsenate of lead used without molasses was less effective in protecting the trees, although it killed some beetles and it was to an extent repellent to them. Lime in the amount in which it is added to an arsenate-of-lead spray was not repellent.

"Forty per cent nicotin sulphate applied with water at the rate of 1:600, with or without soap, was effective as a contact spray. Weaker dilutions of nicotin sulphate and soap carbolic acid solutions, although apparently effective at the time of application, did not have a permanent effect. . . .

"Sweetened arsenate of lead is recommended for cherry trees because of its efficiency in killing the beetles and because its effect is continuous in favorable weather. Rain destroys the effectiveness of this spray. The combination found most useful is 5 lbs. of arsenate of lead, 1.5 gal. of molasses, and 50 gal. of water."

A bibliography of 25 titles is included.

Hyperaspis binotata, a predatory enemy of the terrapin scale, F. L. SIMANTON (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 5, pp. 197-205, pls. 2, fig. 1).—The economic importance of this coccinellid beetle (H. binotata) as an enemy of lecanium scales was impressed upon the author during the course of investigations of the terrapin scale, previously noted (E. S. R., 35, p. 156). The adult beetles do not feed upon the mature scales, but destroy the young and also attack aphids and other soft-bodied insects, being particularly effective in controlling the cottony maple scale and terrapin scale. The beetle occurs in a large part of the territory east of the Mississippi River, being most abundant in the Atlantic States from Connecticut to Maryland, but is common from New Jersey to Illinois, and even extends west of the Mississippi in some States to the semiarid region.

Technical descriptions are given of its life stages. The eggs, which are salmon colored, are deposited singly on twigs adjacent to the host. The life cycle requires 39 days and is as follows: Incubation, 7 days; first instar, 3 days; second instar, 2 days; third instar, 3 days; fourth instar, 12 days; and pupa, 12 days.

Wireworms destructive to cereal and forage crops, J. A. Hyslop (U. S. Dept. Agr., Farmers' Bul. 725 (1916), pp. 10, figs. 6).—This is a general discussion of wireworms and their control based upon the author's investigations, previously noted (E. S. R., 32, p. 555).

Prothetely in the elaterid genus Melanotus, J. A. Hyslop (Psyche, 23 (1916), No. 1. pp. 3-6, pls. 2, fig. 1).

Elateridæ and Throscidæ of the Stanford University expedition of 1911 to Brazil, J. A. Hyslop (Psyche, 23 (1916), No. 1, pp. 16-21, pl. 1, fig. 1).

Observations on the life history of Meracantha contracta, J. A. Hyslop (Psyche, 22 (1915), No. 2, pp. 44-48, pl. 1, figs. 2).

Notes on the habits of weevils, W. D. PIERCE (Proc. Ent. Soc. Wash., 18 (1916), No. 1, pp. 6-10).

The buff-colored tomato weevil (Desiantha nociva), W. W. FROGGATT (Agr. Gaz. N. S. Wales, 26 (1915), No. 12, pp. 1065, 1066).—This weevil has a wide range over the eastern and southern coasts of Australia. In New South Wales it damages the young buds and shoots of fruit trees and vines in early summer, but was not known as a serious field-crop pest until 1915.

Beekeeping in Wisconsin, N. E. and L. V. France (Wisconsin Sta. Bul. 264 (1916), pp. 3-28, figs. 11).—A general account based upon many years' experience, the senior author having been state apiary inspector for a period of 18 years.

Texas beekeeping, L. H. Scholl (Texas Dept. Agr. Bul. 24, 2. ed. (1912), pp. 142, flys. 115).—A second edition of this manual (E. S. R., 27, p. 864).

Annual reports of the Bee Keepers' Association of the Province of Ontario, 1913 and 1914 (Ann. Rpts. Bee Keepers' Assoc. Ontario, 1913, pp. 72; 1914, pp. 78, fig. 1).—The proceedings of the annual meetings of the association for the years 1913 and 1914.

Horismology of the hymenopterous wing, S. A. Rohwer and A. B. Gahan (Proc. Ent. Soc. Wash., 18 (1916), No. 1, pp. 20-76, figs. 11).

British ants, their life history and classification, H. St. J. K. Donisthorpe (Plymouth, England: William Brendon & Son, Ltd., 1915, pp. XV+379, pls. 18, figs. 92; rev. in Science, n. ser., 43 (1916), No. 1105, pp. 316-318).—This comprehensive guide to the study of the British ants is based upon the author's twenty years of labor and experience. In the introduction (pp. 3-64) the external and internal structure, life history, psychology, geographical distribution, geological record, collecting, and observation are considered, following which the indigenous genera and species (pp. 65-334) and cosmopolitan and introduced species (pp. 334-350) are dealt with.

A bibliography of 15 pages and a systematic index to British ants and myrmecophiles are appended. The review is by W. M. Wheeler.

Two new species of Cerceris, N. BANKS (Ent. News, 27 (1916), No. 2, pp. 64, 65).

A revision of the Ichneumonidæ based on the collection in the British Museum (Natural History), with descriptions of new genera and species, C. Morley (London: Brit. Mus. Nat. Hist., 1915, pt. 4, pp. XII+167, pl. 1).—This fourth part of the work previously noted (E. S. R., 31, p. 656) deals with the tribes Joppides. Banchides, and Aiomyides of the subfamily Ichneumoninæ.

Descriptions of six new species of ichneumon flies, R. A. Cushman (*Proc. U. S. Nat. Mus.*, 48 (1915), pp. 507-513).—The species here described as new are *Bassus carpocapsæ*, Aenoplex carpocapsæ, A. plesiotypus, and Glypta brevis reared from the codling moth, at South Acton, Mass., Vienna, Va., Alameda, Cal., and French Creek, W. Va., respectively; Notopygus virginiensis from Vienna, Va.; and Idechthis nigricoxalis reared from Euzophera semifuneralis at Youngstown, N. Y.

Some new chalcidoid Hymenoptera from North and South America, A. A. Girault (Ann. Ent. Soc. Amer., 8 (1915), No. 3, pp. 272-278).—Four genera, 6 species, and 2 varieties are here described as new. Of these Eunotus americanus, reared from Eriopeltis festucæ at Portland, Me., and Anagrus armatus nigriceps, reared from eggs of Empoasca rosæ at Corvallis, Oreg., are of economic importance.

Descriptions of new genera and species, with notes on parasitic Hymenoptera, A. B. Gahan (Proc. U. S. Nat. Mus., 48 (1915), pp. 155-168).—In this paper descriptions are given of three species of Ichneumonoidea and two genera and ten species of Chalcidoidea new to science, including Hyposoter interjectus reared from Prodenia ornithogalli at Arcola, Miss.; Nepiera benevola from Eurymus eurytheme at Salt Lake, Utah; Aphæreta sarcophagæ from Sarcophaga kellyi at Wellington, Kans.; Liodontomerus perplexus and Trimeromicrus maculatus n. g. and n. sp., at Yuma, Ariz.; Habrocytus medicaginis at Glendale, Cal., and Tetrastichus venustus at Corcoran, Cal., from alfalfa seed pods infested with Brucophagus funcbris; Anastatus semiflavidus from Hemileuca oliviæ at Koehler, N. Mex.; Eupteromalus sarcophagæ from S. kellyi at Dodge City, Kans.; Euplectrus insuctus from Lorema accius at Lakeland, Fla.; Diaulinus insularis from Agromyza inæqualis at Rio Piedras, P. R.; and Tetrastichus euplectri from Euplectrus platyhypenæ at Tallulah, La.

New chalcidoid Hymenoptera, A. A. GIRAULT (Ann. Ent. Soc. Amer., 8 (1915), No. 3, pp. 279–284).—One genus and 8 species are here described as new to science, among which is Aphidencyrtus aspidioti, reared from Aspidiotus perniciosus at Lansing, Mich. Coccidencyrtus ensifer is recorded as reared from Aspidiotus juglans-regiæ at Muskegon, Mich.

Chalcidoidea bred from Glossina morsitans in Northern Rhodesia, J. WATERSTON (Bul. Ent. Research, 6 (1915), No. 1, pp. 69-82, figs. 5).—Three species representing as many widely separated groups in the superfamily Chalcidoidea are considered, two of which are described as new to science.

Two new Mymaridæ from the eastern United States, A. A. GIRAULT (Ent. News, 27 (1916), No. 2, pp. 69, 70).

Notes on some sawfly larvæ belonging to the genus Dimorphopteryx, W. MIDDLETON (Proc. U. S. Nat. Mus., 48 (1915), pp. 497-501, pl. 1, jigs. 4).— These notes relate to Dimorphopteryx castaneæ on chestnut at Falls Church and Wiehle, Va., and Blythedale, Md.; D. autumnalis on red oak at Falls Church and Wiehle, Va.; D. quercivora on red oak at Tomahawk Lake, Wis.; and D. errans on birch and linden.

Ticks: A monograph of the Ixodoidea.—Bibliography of the Ixodoidea, II, G. H. F. NUTTALL and L. E. ROBINSON (Cambridge: University Press, 1915, pp. [4]+32).—This addition to the bibliography previously noted (E. S. R., 25, p. 858) lists 462 papers, a large proportion of which have appeared since the publication of the first part.

Ticks: A monograph of the Ixodoidea, III, The genus Hæmaphysalis, G. H. F. NUTTALL and C. WARBURTON (Cambridge: University Press, 1915, pp. NIII+349-550, pls. 9, figs. 143).—The authors recognize 50 species and varieties, including the three species H. spinulosa, H. obtusa, and H. numidiana, the validity of which is somewhat doubtful. The synonymy and references relating to publications which deal with the genus Hæmaphysalis and the generic characterization are followed by keys for the determination of the species of the genus, including males, females, nymphs, and larvæ, so far as known. Specific descriptions of valid species of the genus and of their varieties, which take up the greater part of the work (pp. 362-506), are followed by an account of the geographical distribution and hosts of the genus; a list of condemned and doubtful species of Hæmaphysalis, including their synonymy and literature; notes on the biology of Hæmaphysalis (pp. 518-547), by G. H. F. Nuttall; and an index to valid species of the genus, together with a list of collections in which the types are to be found.

The cassava mite, S. Leefmans (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 14 (1915), pp. 35, pls. 3; abs. in Rev. Appl. Ent., Ser. A, 3 (1915), No. 11, p. 632).—The red spider which injures cassava in Java is Tetranychus bimaculatus or closely related to it. Stripping and burning the leaves is the only remedial measure thus far found to give satisfactory results.

The leaf blister mite of pear and apple, A. L. QUAINTANCE (U. S. Dept. Agr., Farmers' Bul. 722 (1916), pp. 6, figs. 4).—A reprint of Bureau of Entomology Circular 154, previously noted (E. S. R., 27, p. 565).

On a widely distributed gamasid mite (Leiognathus morsitans n. sp.), parasitic on the domestic fowl, S. Hirst (Bul. Ent. Research, 6 (1915), No. 1, pp. 55-58, figs. 3).—L. morsitans, here described as new, is said to have a very wide distribution in Africa and also to be found in Mauritius, China, India, and South America. It appears to be the common bloodsucking gamasid mite of poultry in these countries.

On some new acarine parasites of rats, S. Hirst (Bul. Ent. Research, 6 (1915), No. 2, pp. 183-190, figs. 8).—Four mites from rats are described for the first time, one being a new species of Lælaps which occurs in Ceylon, India, Africa, and South America, while the three others are larval forms of Trombididæ collected in India.

Two Mexican myrmecophilous mites, N. Banks (Psyche, 22 (1915), No. 2, pp. 60, 61, figs. 2).

FOODS-HUMAN NUTRITION.

The infection of foods by bacteria, M. Bornand (*Bul. Soc. Vaud. Sci. Nat.*, 5. scr., 50 (1915), No. 187, pp. 589-619).—Information is given regarding the infection of milk, bread, eggs, meat, and drinks by pathogenic bacteria. The most effective preventive measures are thought to be rigorous inspection of all places where foods are prepared, handled, and sold; protection from insects, especially flies, by suitable screening; and personal inspection.

Feeding experiments with Bacterium pullorum.—The toxicity of infected eggs, L. F. Rettger, T. G. Hull, and W. S. Sturges (Jour. Expt. Med., 23 (1916), No. 4, pp. 475-489).—Earlier work by the senior author (E. S. R., 31, p. 171) on the bacteriology of normal, fresh eggs is referred to and attention is called to the widespread occurrence of Bacterium pullorum in eggs and its possible significance in food poisoning.

The investigation here reported consisted of two parts—a study of the toxicity of *B. pullorum* when administered orally, either with food or by means of a pipette, and also an investigation of the heat tolerance of *B. pullorum* in infected eggs which were prepared for edible use by the ordinary processes of boiling, coddling, frying, etc.

Laboratory animals (rabbits, kittens, guinea pigs, and white rats) were fed varying amounts of water suspensions of cultures of several different strains of *B. pullorum*. Post-mortem examinations were made of the animals which died and also of control animals, the results of the experiments being reported in detail.

The results of these tests showed that "eggs which harbor *B. pullorum* in the yolk in large numbers may produce abnormal conditions, when fed, not only in young chicks, but in adult fowls, young rabbits, guinea pigs, and kittens. The toxicity for young rabbits is most pronounced, the infection usually resulting in the death of the animals. In kittens the most prominent symptoms are those of severe food-poisoning with members of the paratyphoid group of bacteria."

Fresh eggs were infected with *B. pullorum* by injecting a small amount of water suspension of the organism into the yolk by means of a sterile hypodermic syringe. The infected eggs were incubated from three to five days and then cooked in different ways, after which they were examined for the presence of the organisms. These tests showed that poaching the eggs for from one-half to four minutes rendered them sterile. Also no visible organisms were recovered from infected eggs which had been scrambled. In the case of fried and coddled eggs the organisms were recovered from the cooked eggs in some cases and not in others. Even boiling the eggs for four minutes did not in every instance destroy the organisms, this resistance being attributed by the authors to the protection afforded by the shell, the egg white, and the yolk itself.

The authors state that the possibility of danger from infection with B. pullorum can not be ignored, especially in the case of invalids and young children.

"Ovarian infection of fowls is very common throughout this country. Hence a large proportion of the marketed eggs are infected with B. pullorum. When

such eggs are allowed to remain in nests under broody hens or in warm storage places for comparatively few hours they contain large numbers of the organism.

"Soft boiling, coddling, and frying on one side only do not necessarily render the yolks free from viable bacteria; therefore eggs which have gone through these processes may, like raw eggs, be the cause of serious disturbances in persons who are particularly susceptible to such influences, and especially in infants. That no well-authenticated instances of egg poisoning of this kind are on record does not warrant the assumption that there have been no cases. The etiology of infantile stomach and intestinal disturbances is as yet too little understood; in fact, it may be said that many of these disorders have no known cause, and almost as much may be said regarding gastro-intestinal diseases in later life. Furthermore, since the ailments caused by infected eggs would not make themselves felt, presumably, until several days after their ingestion, little or no suspicion would fall upon the eggs. It may be said, too, that the wide distribution of ovarian infection in the domestic fowl has come about only in the last few years, hence its possible danger to man is one of recent development."

Turning green of oysters and their content of heavy metals, F. Liebert (Chem. Weekbl., 12 (1915), No. 44, pp. 978-983).—A summary and digest of data concerning the causes of the green color of certain varieties of oysters. In some cases the color is said to be due to algae and in others to a high copper content.

[Milling and baking tests of wheat] (North Dakota Sta., Rpt. Dickinson Substa., 1913, pp. 20-22).—A brief report is made of the results of milling and baking tests made upon 8 samples of wheat.

A study of certain conditions which affect the activity of proteolytic enzyms in wheat flour, C. O. Swanson and E. L. Tague (Jour. Amer. Chem. Soc., 38 (1916), No. 5, pp. 1098–1109).—The experiments here reported were carried out in continuation of previous work (E. S. R., 30, p. 164), and were designed to study the effects of a number of conditions on the activity of proteolytic enzyms in wheat flour, especially the effects of the inorganic compounds, potassium dihydrogen phosphate, potassium orthophosphate, potassium hydroxid, potassium sulphid, ammonium chlorid, calcium chlorid, and hydrochloric acid, and the organic substances, dried egg albumin, egg albumin digested in water at different temperatures, and casein. Descriptions are given of the method used, which was that of titration with formol to determine the amount of amino nitrogen present in the flour and as a means of measuring the protein cleavage due to proteolytic enzyms present.

Of the various salts tried, ammonium chlorid and calcium chlorid had the greatest accelerating effect on the rate of protein cleavage. "The proteolytic enzyms present in wheat flour caused a more rapid hydrolysis of the proteins when desiccated egg albumin was present, but not when casein was used."

The nature of the dietary deficiencies of the wheat embryo, E. V. McCollum, Nina Simmonds, and W. Pitz (Jour. Biol. Chem., 25 (1916), No. 1, pp. 105-131, figs. 19).—The authors refer to earlier work, especially that reviewed (E. S. R., 33, p. 666; 34, pp. 367, 368; 35, p. 166), and discuss the results of these earlier investigations briefly, in so far as they bear on human nutrition. The method pursued in the work by the authors is based on the following line of reasoning: "If a single natural food product fails to nourish an animal adequately, it may be due to (a) lack of sufficient protein or to proteins of poor quality; (b) an unsatisfactory mineral content due either to inadequacy of certain elements in amount, or to unsatisfactory proportions among them; (c) an inadequate supply of the fat-soluble A; (d) of the water-soluble B; (e)

or some toxic substance contained therein. One, two, three, four, or all of these factors may operate in inducing nutritive disturbances."

Experiments with laboratory animals (rats) are reported, in which was studied the effect of feeding wheat embryo alone or with other ingredients.

It is concluded that "the wheat embryo contains qualitatively all the factors essential for the promotion of growth and well-being in an animal, but these are not so proportioned that it can serve as a satisfactory diet without several modifications. The mineral content must be modified in certain respects before growth can proceed at all.

"The character of the proteins is excellent; no other proteins from plant sources which we have studied are superior to them. Rations containing but 10 per cent of these proteins are wholly adequate for growth at the maximum rate.

"Both the fat-soluble A and the water-soluble B, the factors which must be supplied by an adequate diet, but whose chemical natures are as yet unknown, are present; the first, in moderate concentration; the second, in very high concentration, as measured by the needs of the growing animal. Two per cent of wheat embryo supplies enough of the water-soluble B to promote growth at the normal rate for several months."

The wheat germ contains a substance which is toxic to animals. This factor is found in the fat fraction and is to a great extent removed by ether extraction. It has not yet been determined whether the toxicity is due to the chemical nature of the fats or to some substance associated with them.

The use of the butia palm as a food, J. Puig y Nattino (Insp. Nac. de Ganaderia y Agr. [Uruguay], Bol. 16 (1915), pp. 18).—The palm herein described is an ornamental tree from which a number of food products are obtained. Analyses are given of the fruit, seeds, fiber, leaves, and the juice of the shoots (from which a honey is made).

The preparation and utilization of yeast as food, W. VÖLTZ (*Ztschr. Spiritusindus.*, 39 (1916), Nos. 7, pp. 53, 54; 8, pp. 64, 65).—In continuation of previous work (E. S. R., 34, p. 165), the author reports experimental data regarding the composition, digestibility, and uses of brewery yeast and of yeast cultivated in a medium of sugar and inorganic salts.

Dried yeast containing 95 per cent of water-free material was found to contain from 50 to 60 per cent of protein, 2 to 4 per cent of fat, 25 to 30 per cent of carbohydrate, 6 to 8 per cent of ash, and nearly 2 per cent of phosphatids. In digestion experiments with men the protein, fat, and nitrogen-free extract were 86, 70, and 100 per cent digested, respectively, and the energy was 88 per cent available.

Honey in antidiabetic diet, A. Y. Davidoff (Russ. Vrach, 14 [1915], No. 26; abs. in Jour. Amer. Med. Assoc., 65 (1915), No. 16, p. 1412).—Observations in seven cases of diabetes of the effect of using honey in the diet as a substitute for sugar and other sweet foodstuffs indicate that it prevents acetonuria and diminishes the sugar content of the urine.

The content of stems in Java tea and the testing of tea, J. J. B. Deuss (Chem. Weekbl., 13 (1916), No. 3, pp. 66-71).—Analytical data are given showing the percentage of stems in different kinds of tea. The more expensive brands of tea were found to contain a higher percentage of stems than the less expensive kinds, indicating that the evaluation of tea should not be made on the basis of stem content.

The composition of Hungarian wines, M. Vuk (Kisérlet. Közlem., 18 (1915), No. 5-6, pp. 813-830).—Data are given which show the composition of Hungarian wines, principally from the output of 1913, and some general information regarding the production and exportation of wines during the year 1913.

[Food and drug anlyses], E. F. Ladd and Alma K. Johnson (North Dakota Sta., Spec. Bul., 4 (1916), No. 3, pp. 72-80).—This part of the bulletin contains a report on prepared mustard by R. E. Remington, which includes analytical data. Information is also given regarding some proprietary medicines examined, and the results are reported of the analysis of several samples of foods and beverages.

The economics of electric cooking, P. W. Gumaer (Univ. Missouri Bul., 16 (1915), No. 27, pp. 62, figs. 37).—The object of the investigation here reported was to ascertain some of the factors which increase the economy of electric cooking. Tests were made with three commercial and several especially constructed experimental ovens, in order to determine the amount of energy consumed in cooking, and the best methods of preparing different foods for the electric oven. The details of construction of the ovens are described in the bulletin, as are also the method of measuring by means of copper-constantan thermocouples, the temperatures of the ovens and the internal temperature of the foods during cooking. The experiments furnished considerable information as to the losses of energy in electric ovens due to convection and radiation, preheating, and the opening of the oven door.

"The energy lost when the door of an electric oven is opened for 15 seconds was determined for various oven temperatures. For an oven temperature of 200° C. (392° F.) used in baking bread, biscuits, etc., the loss due to opening a 12-inch by 18-inch oven door for 15 seconds amounted to 12 watt hours. At 5 cts. per kilowatt hour for electric current this would mean a cost of 0.06 ct. each time the door was opened for a period of 15 seconds.

"Since the purpose of cooking food is not to put as many heat units as possible into the food, but is rather to improve its flavor, and to increase its digestibility, the steam boiler method of determining efficiency is not applicable to electric ovens."

Considerable space is devoted to a discussion of the general efficiency of electric ovens. "In order to compare the cost of cooking in various electric ovens, a method proposed for indicating the relative efficiency of the electric ovens is to specify the amount of the preheating and the radiation losses at the required oven temperatures."

Experiments were undertaken to determine the most satisfactory and economical temperatures for roasting beef. Twenty-two rib roasts of like size and quality were boned, rolled, and roasted at 100, 120, 140, 160, and 180° C., the time required for the cooking, the loss in weight, and the amount of energy consumed at each temperature being measured. To secure uniform results in the degree to which the meat was cooked, each piece was removed from the oven when the interior reached a definite temperature. An inner temperature of 55° was taken to indicate meat that was rare, 65° medium rare, and 75° well-done meat, since these figures conformed to the usage of other experimenters. A table is given which shows the temperatures of the roasts on removal from the oven which gave the most satisfactory results as regards quality of the meat. The searing of the meat previous to roasting was accomplished in an open aluminium dish over a heating coil, this method being found to result in a saving of 5 cts., on the basis of 5 cts. per kilowatt hour for electric current, over the method of heating the whole oven up to 250° for 10 to 15 minutes in order to sear the outside of the meat.

Figures are given which show the time temperature curves for the inside of the roasts for different oven temperatures, which are of especial interest in cooking studies. "The shortest time of roasting was at 160° .

"The percentage loss of weight of the roasts was found to increase with the oven temperature used."

Other figures show the effect of oven temperature on the time of cooking of beef roasts and on losses in weight and the energy required to roast beef under different conditions.

"The energy required for roasting a rolled rib roast of beef in three types of electric ovens was determined for oven temperatures from 100 to 180°. The most economical temperature for preparing rare and medium-rare roasts was found to be 100° in each oven. For well-done roasts 120° is the most economical temperature."

A series of experiments were also carried out on the baking of biscuits, bread, and sponge cakes, in order to determine the range of temperature in which each of these could be most satisfactorily and at the same time economically baked. Curves are given which show the effect of oven temperature on the time of baking and the percentage of loss in weight and the energy required to bake each article under different conditions.

"The range of oven temperatures for baking biscuits was found to be from 200 to 240°. Starting with the oven at the required temperature, the energy used in making biscuits is practically the same for all oven temperatures. If it is necessary to heat up the oven from room temperature, the most economical oven temperature is the lowest which will give satisfactory results; i. e. about 200°.

"The range of temperatures for baking a small-sized loaf of bread was found to lie between 180 and 240°. Starting with the oven at the required temperature, the most economical temperature for baking bread is between 220 and 240°. When preheating is included, the most economical temperature for a small-sized loaf was found to be between 200 and 215°.

"The range of temperature for baking sponge cake was found to lie between 170 and 190°. For baking sponge cake the most economical oven temperature is the highest temperature which will give satisfactory results; i. e., about 190°. . . .

"For baking at the higher temperatures a heating element in the upper part of the oven is necessary to get the best results. Without the upper heating coil the bread, cake, or biscuits will burn on the bottom before they are satisfactorily browned on top. For the lower temperatures this upper coil is unnecessary."

It was also a feature of the experiments to determine the most economical thickness of heat insulation. It was concluded that "with electricity at 5 cts. per kilowatt hour and allowing an interest and depreciation charge of 25 per cent, the most economical thickness of kieselguhr insulation was found for domestic use to lie between 3 and 4 inches."

In conclusion the author emphasizes the importance in electric cooking of accurate temperature measurements, adequate means of controlling the temperature of the food, and the formulation of definite rules or directions for the cooking of each article. A number of suggestions are given for the construction and operation of electric ovens to secure the best results.

Nutritional physiology, P. G. STILES (Philadelphia and London: W. B. Saunders Co., 1916, 2. ed., pp. 288, pls. 4, figs. 19).—The first edition of this book has been previously noted (E. S. R., 28, p. 763).

Hunger and food, G. J. Peirce (Sci. Mo., 2 (1916), No. 2, pp. 181–188).—This article considers some economic aspects of the food supply.

The amino-acid minimum for maintenance and growth, as exemplified by further experiments with lysin and tryptophane, T. B. OSBORNE, L. B. MENDEL, ET AL. (Jour. Biol. Chem., 25 (1916), No. 1, pp. 1-12, figs. 4).—In explanation of the fact that adequate growth has never been obtained with rations in which the nitrogenous components do not furnish sufficient proportions of

amino acids, such as tryptophane, lysin, or cystin, the authors state that an essential feature of the construction of new tissue is a synthesis of new protein. Growth will, therefore, be limited by any factor preventing this synthesis, such as the lack of any component amino acid which can not be manufactured directly in suitable amounts by the body. The authors review briefly earlier experiments by themselves and others, which show the effects of tryptophane, lysin, and cystin upon growth when added to an otherwise deficient ration.

Additional experiments with laboratory animals (rats) are reported which show that "the need for tryptophane and lysin is governed by the 'law of minimum,' the rate of growth increasing with increasing amounts of these amino acids furnished by the food until the normal rate is attained. When larger quantities of these amino acids are supplied growth is not made more rapidly, for the construction of new tissue is no longer limited by deficiencies in the requisite supply of any element of the food, but by the natural capacity of the animal to grow."

The energy content of the diet (Sci. Mo., 2 (1916), No. 3, pp. 279-306).—The following four papers form a symposium and were read before the Section of Physiology and Experimental Medicine of the American Association for the Advancement of Science, at Columbus, Ohio, in December, 1915:

Proteins in growth, by Ruth Wheeler (pp. 279–282).—This paper summarizes the results of recent investigations relative to the rôle of amino acids in nutrition and emphasizes the importance of the amino acid content, as well as other characteristics of proteins, in determining their food value.

The mineral nutrients in practical human dietetics, by E. B. Forbes (pp. 282-289).—In this article the author enumerates the functions of the mineral elements in metabolism and discusses their importance in the diet. The bulk of the material is essentially the same as that noted in an earlier paper (E. S. R., 35, p. 62).

The chemical nature and physiological significance of so-called vitamins, by C. Voegtlin (pp. 289-293).—Recent investigations by the author and others are summarized and the importance of vitamins in practical dietetics is considered. A table is given showing the common foods which are relatively rich and relatively poor in antineuritic and antiscorbutic properties.

Food selection for rational and economical living, by C. F. Langworthy ^a (pp. 294-306).—The author considers at length a number of factors which should be taken into account in securing an adequate and economical diet which at the same time gives satisfaction. Information is given regarding the selection, preparation, and cooking of foods, and the planning of meals.

As a guide for the housekeeper in the wise selection of food materials for a meal or for a day's ration, and also as a means of checking up and criticizing meals served, the author classifies the common foods into five groups, corresponding to their distinctive functions in nutrition. "The groups may be described in terms of the dietitian as follows: (1) Foods in which protein bears a higher proportion to fuel value than it does in the well-chosen diet as a whole; (2) those in which fuel value is high in proportion to protein, owing chiefly to the presence of much starch; (3) those in which fuel value is high, owing to the large percentage of fat; (4) those whose chief value is mineral constituents and vegetable acids (the latter important from the standpoint of flavor as well as of body needs); and (5) those which (like the foods in Groups 2 and 3) have a high fuel value, but in this case due to the presence of sugar. From the standpoint of fuel value only, it is obvious that Groups 2 and 5 could be combined. From the standpoint of the well-chosen and palatable meal, on the other

^a Sci. Amer. Sup., 81 (1916), Nos. 2100, pp. 210, 211; 2101, pp. 230, 231.

hand, they should be kept distinct, since sugar is frequently as important as a flavor as it is as a food."

In discussing the practical use of this grouping of foods by the housekeeper, sample menus for the day's meals are given which contain food materials which are wholesome but combined in such a way as to furnish an excess of protein, fat, and carbohydrate.

ANIMAL PRODUCTION.

Silage investigations: Normal temperatures and some factors influencing the quality of silage, C. H. Eckles, O. I. Oshel, and D. M. Magruder (*Missouri Sta. Research Bul. 22* (1916), pp. 3-32, figs. 7).—In these investigations various types of silos were used, including the concrete, iron, stave, and tile silos, as well as small experimental silos. Temperature readings were taken by means of electrical resistance thermometers placed in half-inch iron pipe, and the wires carried to the surface of the silage so that readings could be taken.

It was found that in the climate of Missouri the temperature of silage when put in the silo will generally range from 75 to 95° F. The temperature rises from 3 to 15°, reaching a maximum in from eight to twelve days. From this point on the temperature of the silage slowly declines. Where sufficient moisture is present and the silage is well packed the highest temperature will rarely exceed 100°. By December 1 the temperature reaches a point between 60 and 70°, and the lowest point, 50 to 60°, is reached by March.

The temperature in the silage in the early stage is influenced to some extent by the temperature of the atmosphere at the time of filling, and of the water used, if any be added. The greatest factor causing variations in the temperature in a silo is the amount of air contained in the silage. It was found, experimentally, that the presence of air and the resulting growth of mold increased the temperature in every case. The material used in the construction of the silo has but little, if any, influence upon the temperature of the silage.

In an experiment planned to determine the relation of the temperature in the silo to the quality of the silage produced, six cans holding about 10 gal. each were filled with corn from a large concrete silo while it was being filled. The corn was thoroughly packed in the cans and covers provided which would slip inside the cans. The cans were then placed in a screw press and heavy pressure applied. The lids were securely fastened before the pressure was removed and the cover was sealed around the edges with paraffin to exclude the air. Two cans were placed in a cooling room at a temperature of approximately 50°, two at a temperature of 68°, and the other two at a temperature of 100°. Twenty-three days after filling one can from each lot was opened, the silage compared as to appearance, odor, and taste, and samples were taken for acidity, moisture determinations, and chemical analysis. The three remaining cans were opened 58 days after filling.

No marked difference in the composition of the silage fermented at the three temperatures used was obtained. The acidity was decidedly the highest in the lot at medium temperatures. The protein showed practically no variation, and the ether extract was practically the same in all, or was within the limits of error in making such analyses. There was some difference noticeable in the figures for crude fiber and nitrogen-free extract. In each case the percentage of crude fiber decreased between the date of the first sample and that of the second. It would seem safe to attribute this to the effect of the fermentation. The nitrogen-free extract was the highest in the lot at medium temperature and the lowest at the high temperature.

The highest loss in dry matter occurred at the highest temperature. It was evident from the odor and taste that there was considerable difference in the character of the fermentation which took place at the three temperatures, but all three lots would have passed as normal silage, although the lot at medium temperature was rather better than the lot at 50°, while that fermented at 100° was ranked slightly superior to the medium. Apparently a medium temperature from 77 to 85° is the most favorable for silage fermentations, but the results indicate that the limits can be extended to 60 and 100° at least without any material difference in the results. Temperatures much above this are not desirable, since such a temperature must mean the oxidation or destruction of some of the silage material to furnish the heat.

It is deemed evident that the quality of the silage produced will not be influenced by any effect upon temperature of the material used in constructing the silo, as analyses of silage from the wall and center of silos of various types of construction showed no difference in composition due to the materials used.

A comparison of silage from a large silo and of silage from the same corn put into a small experimental silo showed the quality to be the same, as judged by appearance and by chemical analysis. For all purposes, except studying temperature changes, the small silo is believed sufficiently accurate for experimental purposes. The experimental silos used were water tanks 3 ft. in diameter and 6 ft. high and constructed of 2-in. cypress. A wooden cover was made to fit loosely and was provided with a ring of felt around the edge to make a reasonably tight joint. Weight was applied in the form of 1,500 lbs. of rock. This was estimated to equal the pressure to which silage is subjected at a point one-third of the distance from the top of a silo containing 28 ft. of average silage.

Feeding coconut cake on grass, K. J. J. Mackenzie and E. H. Powell (Jour. Bd. Agr. [London], 23 (1916), No. 2, pp. 117-123).—Feeding experiments with steers indicate that coconut cake, when suitable in price, is a valuable feed for steers on grass, but that it is not very palatable and so should be gradually introduced into a mixture of palatable feeds. It is advised that the amount be restricted to 50 per cent of the concentrated ration, and that it be fed with something rather constipating, such as cotton cake. It is stated that a daily ration of 4 lbs. of a mixture of coconut cake, cotton cake, and linseed cake, 3:3:2, appears to give the best results.

The industrial utilization of the waste product of rice hulling, N. Novella (Gior. Risicolt., 5 (1915), No. 15, pp. 242, 243).—The results of feeding experiments are given which indicate that the flour waste product from rice hulling is easily digested and highly nutritious. The readiness with which the product becomes sour is an obstacle to its general use. It is suggested that it be converted into cakes, in which form it would keep for a long time and could be easily transported.

The nutrition of farm live stock, especially cattle, W. Klein (Biochem. Ztschr., 72 (1915), No. 3-4, pp. 169-252, figs. 2).—This article reports a comparative study made of the Zuntz, Regnault-Reiset, and Pächtner methods of metabolism measurement.

It is concluded that the Zuntz method of gas interchange measurement is the best for determining the influence of the biological processes on the gas interchange, but there appears to be a close agreement with all three methods. The calculation of the energy balance alone by respiration experiments, that is O₂ consumption and CO₂ elimination, when compared with the chemical analysis of the intake and outgo was in close agreement.

It was found that the castration of bulls was without influence on the energy assimilation. It was demonstrated that more than 14 per cent of the total carbon dioxid elimination in cattle was by way of the skin and intestines.

The results of these experiments showed a higher energy consumption for older steers than those secured by Dahm (E. S. R., 25, p. 674), but were in close agreement with the Armsby calorimeter results (E. S. R., 15, p. 799). It was apparent that the maintenance requirements in the various ages of cattle were in proportion to the body surface.

Nondisjunction as proof of the chromosome theory of heredity, C. B. Bridges (Genetics, 1 (1916), Nos. 1, pp. 1-52, pl. 1, figs. 8; 2, pp. 107-163, pl. 1, fig. 1).-In this paper experimental proof is offered that "particular chromosomes, the X chromosomes, are the differentiators of sex; the X chromosome constitution of an individual is the cause of the development by that individual of a particular sex, and is not the result of sex already determined by some other agent. The sex is not determined in the egg or the sperm as such, but is determined at the moment of fertilization; for the X sperm of the male gives rise to a female when it fertilizes an egg containing an X, but to a male if it fertilizes an egg containing a Y or no sex chromosome at all. Likewise the Y sperm of a male gives rise to a female when fertilizing an XX egg and to a male when fertilizing an X egg. These facts in connection with the fact that an X egg of a female produces a male if fertilized by an X sperm prove that the segregation of the X chromosomes is the segregation of the sex differentiators. The presence of two X chromosomes determines that an individual shall be a female, the presence of one X that the individual The origin of these chromosomes whether maternal or shall be a male. paternal is without significance in the production of sex.

"The Y chromosome is without effect upon the sex or the characters of the individual, for males may have one Y, two Y's, or may lack Y entirely (males lacking Y are sterile); and females may have one or two supernumerary Y's with no change in appearance in any case."

A bibliography of references is appended.

A sex-limited color in Ayrshire cattle, E. N. Wentworth (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 4, pp. 141-147).—It is stated that a case which seems to fall under the sex-limited group is found in the inheritance of black and white as alternative to red and white in Ayrshire cattle. If the factor for the black and white color is represented by <math>B, the hereditary constitutions are as follows: BB is always black and white; bb is always red and white; and Bb is always black and white in the male and red and white in the female.

In breeding experiments at the Kansas Experiment Station all of the nine possible matings were discovered. From the data obtained it appears that the black and white color of Ayrshire cattle behaves in an ordinary sex-limited manner similar to the horns in sheep as discussed by Wood ^a and the rudimentary mammae in swine as reported by the author (E. S. R., 27, p. 769).

It is concluded that black and white color is a simple allelomorph of red and white color in Ayrshire cattle. In the male the black and white character is dominant and in the female the red and white character is dominant. Males heterozygous for the two characters are black and white, while females heterozygous for the two characters are red and white.

Sheep raising in Wisconsin, F. Kleinheinz (Wisconsin Sta. Bul. 263 (1916), pp. 19, figs. 11).—This bulletin deals with the opportunities for successful sheep raising in Wisconsin and the methods of care, feeding, and management.

Fish meal as food for pigs, C. Crowther (Jour. Bd. Agr. [London]. 23 (1916), No. 1, pp. 27-33).—Pigs fed fish meal in addition to a basal ration of bran and middlings made 1.35 lbs. greater gains per pig weekly than those fed

the basal ration alone. When slaughtered the fish-fed pigs showed no undesirable appearance, color, or smell in any part of the carcass, and at no stage of cooking could an exceptional smell or flavor be detected.

Large-type swine and fertility, E. N. Wentworth (Breeder's Gaz., 69 (1916), No. 13, pp. 722, 723).—In an investigation conducted at the Kansas Experiment Station 1,000 litters of large-type Poland-Chinas and 1,100 litters of small-type Poland-Chinas were compared for average size. The large type farrowed litters of 7.854 pigs on the average, while the small type farrowed 7.896 pigs, the difference in fertility between the two strains of swine thus being insignificant.

The average amount that the group of large-type sows varied from its average litter, 2.141 pigs per litter, was compared with the average amount that the small-type sows varied from their average litter, 2.146 pigs per litter. The advantage in this case is in favor of the large type, since it is more desirable to have a small deviation; but, again, the difference is not great enough, either practically or theoretically, to be significant.

Swine production in Holland and its development in the last hundred years, H. M. Kroon (Die Schweinezucht in Holland und ihre Entwicklung in den Letzten 100 Jahren. Inaug. Diss., Univ. Bern, 1915, pp. 65, pls. 6).—This dissertation treats of the various breeds of swine found in Holland, their distribution and improvement, methods of care and management, and the general status of the industry.

Experimental results in fattening poultry, M. A. Jull (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 7, pp. 49–52).—In these experiments, conducted in Canada, three lots of birds received corn meal, oatmeal feed, and ground buckwheat as their respective grain rations. The ground feed was mixed with water, allowed to stand for at least twelve hours before feeding, and fed in a batter just thin enough to run out of a pail without difficulty. The birds were fed twice daily, the first feed being given early in the morning and the second one late in the afternoon. All food was removed from the feeding troughs as soon as the birds had satisfied their appetites.

It was found that less grain was required to produce 1 lb. gain in flesh when the birds were fed on corn meal than when fed on a ration of equal parts, by weight, of corn meal, oatmeal feed, and ground buckwheat, or when fed on a ration of pure oatmeal feed, also that the mixed ration was somewhat superior to the oatmeal ration in that respect. It was also shown that less grain was needed to produce 1 lb. gain in two weeks than in three weeks with the three rations, and that the extra profit obtained by feeding three weeks was not sufficient to warrant the practice, so that two weeks' feeding is to be preferred. While oatmeal feed gave the cheapest gains the mixed feed gave the largest profits, with oatmeal feed last in this respect.

The weights between live, dressed, and drawn poultry showed a gradual shrinkage, with much less loss of weight between the live and dressed birds than between the dressed and drawn birds. The difference in profit was also considerable, being in favor of dressing and showing an actual loss in drawing.

The profits derived from poultry fattening were 39.5 per cent on the investment. Efficiency in roaster production, H. R. Lewis (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 6, p. 48).—Experiments conducted at the New Jersey Experiment Stations with Plymouth Rock and White Leghorn cockerels indicated that at nine months of age the Leghorns were matured and would soon become staggy, while the Rocks were in prime condition for slaughter. The average weight of the Rocks was 7.2 lbs., and of the Leghorns 3.8 lbs. The weight of the dressed carcass (weight after bleeding and picking and removing the heads, shanks, and offal) at the same age showed that in the case of the

Plymouth Rocks 75 per cent of the total carcass was available, while in the case of the Leghorns only 67.3 per cent was available. At this age the Barred Plymouth Rocks sold for 27 cts. a pound and the Leghorns for 21 cts.

Meat scrap in the laying ration, H. R. Lewis (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 7, pp. 52, 53).—In these experiments, conducted at the New Jersey Experiment Stations, pen 1 received 25 per cent of meat scrap in its dry mash and pen 2 received 10 per cent. Pen 1 laid 6,711 eggs during the first year, 4,207 the second, and 3,048 the third year, while pen 2 laid 4,639, 4,358, and 2,674 eggs during the respective years.

From the results of the experiments it is concluded that the higher percentage of meat scrap in the dry mash was justified, at least during the pullet year, as the profit above feed was \$127.88 as against \$75.60 in the pen receiving the low percentage of meat scrap. The first year of egg production in the first-mentioned pen was followed by a comparatively low production, whereas the production in the pen which had not been forced during the pullet year was only slightly decreased. The same results seemed to show during the third year, so that the general conclusion is drawn that high production during the pullet year is apt to be followed by decreased production in future years.

The mortality was practically uniform in each pen, the birds in both pens remaining in good condition in general throughout the period. The hatchability in each pen was practically uniform, and the size and weight of eggs in each pen were not noticeably different. Under systems of management where birds are kept for two laying years only, a higher percentage of meat scrap can undoubtedly be advised, as the increased production during the first year will more than balance the difference during the second year.

A study of egg production and some related factors, L. E. CARD (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 6, pp. 42-44). Records kept of laying hens at the Connecticut Storrs Experiment Station showed that a given pen will consume much more oyster shell when laying heavily than when laying less heavily or not at all. Using 32 pens of Single Comb White Leghorns a correlation table was worked out so that this relationship might be expressed mathematically. For this purpose the year was divided into thirteen four-week periods. The number of eggs laid by any given pen during any four-week period was used as the basis of distribution for one system of arrays, while the amount of oyster shell consumed during the same period was used as the basis for the other system of arrays. The coefficient of correlation as worked out from this table was 0.8724+0.0079, showing that a very close correlation exists between the factors under discussion. The same method, when applied to the heavy breeds, viz, Plymouth Rocks, Rhode Island Reds, and Wyandottes, taken collectively, showed a correlation factor of 0.8265 + 0.0096.

Similarly the relation between the amounts of grain and mash consumed and the corresponding egg production was worked out. In the case of the Leghorns there was a close correlation between the amount of mash consumed and the number of eggs laid, i. e., 0.7493+0.0157, while there was practically no correlation between the amount of hard grain consumed and the number of eggs laid, the correlation coefficient in this case being 0.0214-0.0353. The same general result was obtained in the case of the heavy breeds.

It appears from the study thus far conducted that the production during the summer months, except in the case of Wyandottes, is perhaps a better index of the yearly egg yield than is the winter production.

Value of egg shows, A. S. Chapin (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 7, pp. 53, 54).—The methods and plans used in holding annual egg shows at Purdue University are outlined.

The poultry industry, its importance in agricultural development, H. M. LAMON (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 6, pp. 41, 42).—An abstract of a paper presented before the Second Pan American Scientific Congress, giving a general review of the development of the poultry industry in the United States and other countries.

The management of the farm poultry flock, V. G. Aubry (New Jersey Stas. Circ. 49 (1915), pp. 20).—This circular deals with the housing, feeding, care, and management of the farm poultry flock.

The Flemish system of poultry rearing: Scientifically improved, Madame B. A. Jasper (Country Life [London], 37 (1915), Nos. 956, pp. 577, 578, ftg. 1; 957, pp. 635, 636; 958, pp. 672-674, ftgs. 2; 960, pp. 743-745, ftg. 1; 962, pp. 838-840; 964, pp. 913-915; 38 (1915), Nos. 967, pp. 88, 89; 969, pp. 171-173; 971, p. 245; 973, pp. 294, 295; 975, pp. 367-369; 977, p. 437; 979, pp. 8*, 10*; 980, pp. 528-530).—A very comprehensive treatise on the Flemish methods of breeding, incubating, brooding, housing, feeding, care, and management of poultry for meat and egg production.

American pheasant breeding and shooting, E. A. Quarles (Wilmington, Del.: Hercules Powder Co., 1916, pp. 130, figs. 52).—General methods of breeding, feeding, care, and management of pheasants are described.

DAIRY FARMING-DAIRYING.

[Convention of milk and butter producers at Washington, D. C., 1916] (Amer. Food Jour., 11 (1916), No. 6, pp. 244-253).—An account of the convention of milk and butter producers and other dairy interests held at Washington, D. C., May 5 and 6, 1916 (E. S. R., 35, p. 98).

On the change in the composition of the milk of cows, O. ALLEMANN (Milchw. Zentbl., 44 (1915), No. 8, pp. 122, 123).—Analyses are given of colostrum milk and of milk at short intervals after parturition, showing the rapid changes that take place.

Effect of water in the ration on the composition of milk, W. F. Turner, R. H. Shaw, R. P. Norton, and P. A. Wright (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 4, pp. 167-178, fig. 1).—In these studies four different methods of varying the water content of the ration were used: A full v. a limited allowance of drinking water; turnips v. a dry-roughage ration; wet v. dry beet pulp; and green v. dry crimson clover.

Certain individual cows at times produced milk having an abnormal fat content. This effect was apparently independent of the ration, as it occurred not only with the high water-content ration but with the dry as well.

A study of the data obtained in the four series, however, shows that the watery character of the ration has no effect upon the fat content of the milk. There was even less variation in the other milk constituents than in the fat. This indicates that rations of varying water content have no effect upon the composition of milk.

A bibliography of literature cited is given.

The influence of sickness on the composition and characteristics of cow's milk, R. Bergema (Untersuchungen über den Einfluss einiger äusseren und inneren Krankheiten auf die Zusammensetzung und die Eigenschaften der Kuhmilch. Inaug. Diss., Univ. Bern, 1915, pp. 78).—The specific gravity of milk was in general not noticeably altered by sickness of the animal. The chlorin content was in general high. The milk-sugar content often showed a decline, while the fat content was as a rule higher than normal. The diastase content showed an increase of this enzym, and the catalase content was very often high.

The composition of the milk of Egyptian animals, A. PAPPEL and G. HOGAN (Cairo: Dept. Pub. Health, 1914, pp. 12).—An analysis of Egyptian buffalo milk is given.

Effect of pasteurization on mold spores, C. Thom and S. H. AYERS (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 4, pp. 153-166, figs. 3).—Studies were made with spores from pure cultures of a series of molds including several species of Penicillium, of Aspergillus, and of the mucors, with, in some experiments, the addition of Oidium (Oospora) laetis and one strain of Fusarium. These sets of experiments were made to test the temperatures used in pasteurization by the holder process, those used in the flash process, and the effects of dry heat.

In the holder process of pasteurization, in which milk was heated to from 120° to 150° F. and maintained at these temperatures for 30 minutes, the *Mucor racemosus* group and *Rhizopus nigricans*, which are found more frequently than all others of the mucor group combined, were destroyed at 130°. The common green species of Penicillium are mostly dead at 130°; a few stand 135°, but two, one of them an undescribed soil organism, survived 140° for 30 minutes. Among species of Aspergillus, however, the strains of *A. flavus*, *A. fumigatus*, and *A. repens* all survived 145° for 30 minutes, and *A. repens* and *A. fumigatus* both survived 150°. These three species are always found in forage and feeding stuffs; hence, milk is more or less subject to contamination with them. *A. repens* grows very poorly in milk, however, and the examination of a great many cultures of milk and its products has shown that the actual development of *A. flavus* and *A. fumigatus* is comparatively rare. Pasteurization of milk at 145° may therefore be regarded as destroying mold spores completely enough to render them a negligible factor in the further changes found in the milk.

In the flash process of pasteurization, where milk was heated to from 145° to 175° for a period of 30 seconds, the spores of all the molds tested were destroyed with the exception of many spores of one form and occasional spores of three more forms. At 175° only occasional spores of two forms developed.

When the heating process was performed in dry air for a period of 30 seconds at 200°, 31 out of 42 forms of Penicillium and 7 out of 24 forms of Aspergillus were destroyed, but none of the cultures of the mucors. A temperature of 250° over a period of 30 minutes killed all the forms of *Penicillium* spp. tried, but left an occasional living spore in one species of Aspergillus and 3 out of 6 mucors.

Careful study of the cultures showed that the first effect of heating was to delay germination. At times heating to a degree just under the death point delayed germination almost the full length of the usual growing period of the species. There is frequently a survival of a few spores where a majority of the spores die. There may be, therefore, a difference of as much as 20° between the temperature at which an occasional culture is completely killed and that at which cultures of that species are uniformly killed. These results resemble those obtained in determining the thermal death point of bacteria.

Metallic flavor in dairy products, E. S. GUTHRIE (New York Cornell Sta. Bul. 373 (1916), pp. 609-643).—The results of these studies seemed to indicate that there may be a cause of metallic flavor other than direct contact of the dairy product with metal. In several instances it seemed to increase when the product was not in contact with metal.

Buttermilk in sterilized glass bottles developed the flavor in many cases. Of 241 samples of cream in sterilized glass bottles metallic flavor was produced in 79 by inoculation with metallic-flavored buttermilk; and of 157 samples of cream in sterilized glass bottles which were inoculated with individual bacteria 52 showed metallic flavor. It is concluded that the organism that causes metallic

flavor is a member or a strain of the *Bacterium lactis acidi* group. Metallic flavor may develop in cream of either good or poor flavor, and the indications are that enzyms may be a factor in its production.

It was found that high acid content is essential for the development of the flavor. It is possible that electrolytic action plays an important part in its production when the source is directly from metal. The flavor was most likely to appear during the hottest season. It may be that this was noticeable because the degree of acidity of the product is likely to be greater when the temperature is high.

A high fat content seemed necessary for the development of the flavor except in the case of buttermilk. Whenever the flavor was found in whole milk it was always near the surface, in the cream, and it was never observed in skim milk or cottage cheese. For some reason it was often found in buttermilk, but with this exception never in a dairy product low in fat content.

It is deemed difficult to explain why metallic flavor develops to a greater degree in buttermilk than in any other dairy product. It was thought that there might be a relation between the acids of the milk fat and the metallic flavor. Samples of butyric, caproic, caprylic, palmitic, stearic, and oleic acids were obtained, also propionic acid, which is lower in the fatty acid series, and succinic acid, which is a dibasic organic acid and may be found in dairy products. No sign of metallic flavor, however, could be detected in any of these acids.

The flavor appeared spasmodically. Often it could not be detected in butter for several weeks, and sometimes for many months, after which it suddenly appeared for perhaps a few days or possibly for several weeks. During all this time the same utensils were being used on the farms and in the creamery laboratories. Low temperatures often seemed to make the flavor more apparent.

Note on the neutralization of cream in butter manufacture, and the effect on the butter produced, A. A. Ramsay (Dept. Agr. N. S. Wales, Sci. Bul. 16 (1915), pp. 10).—A method of treating cream before manufacturing it into butter, known as "neutralizing and pasteurizing," is described. The term neutralizing, in conjunction with pasteurizing in the method of treating creams for the manufacture of butter, is used to indicate the reducing of the acidity, probably the excessive acidity, of the cream, not to the neutral point but to faint or slight acidity, say, to 0.2 per cent of acid expressed as lactic acid.

Sodium bicarbonate or, as an alternative, washing soda (crystallized sodium carbonate) is generally used on account of its cheapness and because the supply is plentiful. The result of the neutralization or partial neutralization is the formation of the sodium salt of the organic acids and the liberation of carbon dioxid. The carbon dioxid so formed is impeded in its passage through the cold mass of cream on account of the viscosity of the latter. This viscosity is lessened when the cream is heated to 170° F., as in pasteurizing, and the gas then escapes into the air. As it rises through the mass of cream it is claimed that it carries with it mechanically the volatile substances which give the cream an unpleasant smell or taste, as, for example, "food taint," and the heating to 170° assists in the removal of the gas and in the destruction of the micro-organisms present. The result is a product from which unpleasant odors and taints have been removed, and one which, if not absolutely sterile, is very nearly so. Into this mixture the pure culture of lactic bacilli, or "starter," is added, thus making an abundant growth of the lactic bacilli and producing good, clean lactic acid. The carbonates which may be used for the

purpose of either neutralizing or reducing the acidity of cream are sodium bicarbonate, washing soda, anhydrous sodium carbonate, and calcium carbonate.

Although the primary action of the alkaline carbonate or bicarbonate is simply to neutralize the free acids present, there will probably also be some action between the alkali added and the proteid matter present.

There appears to be reason to believe that in chemical composition butter made from neutralized and pasteurized cream should very closely approximate, if not coincide with, butter made from untreated cream. The skill, knowledge, and ability of the butter maker will be the principal factor which will control the amount of curd which will be present in the finished butter. Other things being equal, it appears justifiable, however, to expect somewhat less curd in butter made from neutralized than in that from untreated cream.

The butter industry in the United States, E. Wiest (Columbia Univ. Studies Polit. Sci.. 69 (1916), No. 2, pp. 264, figs. 12).—This is a report of an economic study made of the butter and oleomargarine industries in the United States. The topics discussed are the manufacture of butter, organization for the production of butter, geographic distribution of butter-producing areas, organization for dairy education, grading and judging butter, history and development of the organization of the butter market, the present organization of the butter market, butter prices, adulteration and oleomargarine, and the oleomargarine law and its development.

Test to determine amount of yellow color in a product (Hoard's Dairyman, 49 (1915), No. 11, p. 439).—It is reported that the U. S. Bureau of Standards has found that the color of butter and oleomargarine can be satisfactorily graded by the ratio of its reflecting powers for blue and yellow light.

The yoghourt bacillus, F. Ducháček (Biochem. Ztschr., 70 (1915), No. 3-4, pp. 269-293).—The author conducted comparative experiments with the yoghourt bacillus as described by the workers at the Pasteur Institute and with the bacillus as described by Effront.

There was found to be a difference between these two types as regards the choice of the medium in which they develop. Bacillus E (Effront) developed exceedingly well in all the usual media, while B. bulgaricus was very exacting in this respect, requiring, besides a particular kind of sugar, the addition of lime for the neutralization of the acid, especially in artificial media. The two types differed as to their air requirements, B. bulgaricus growing in an anaerobic medium, while Bacillus E was distinctly aerobic. The two bacteria may also be distinguished by differences in the length of life, B. bulgaricus dying after three months and Bacillus E living for several years.

See also previous notes by Effront (E. S. R., 25, pp. 81, 609, 610) and Bertrand (E. S. R., 25, p. 609).

Studies on Lactobacillus fermentum, J. Smit (Ztschr. Gärungsphysiol., 4 (1915), No. 4. pp. 273-299. figs. 3).—This article reports a morphological study made of L. fermentum.

VETERINARY MEDICINE.

A handbook of veterinary medicine, H. J. Gobert (Aide Mémoire du Vétérinaire Médecine, Chirurgie, Obstétrique, Formules, Police Sanitaire et Jurisprudence Commerciale. Paris: J. B. Baillière & Sons, 1915, pp. VIII+736, figs. 252).—This is a ready reference work for the veterinarian.

Essentials of veterinary law, H. B. Hemenway (Chicago: Amer. Jour. Vet. Med., 1916, pp. XIV+340).—The several parts of this work pertain to (1) legal principles, (2) veterinary practice, (3) governmental control, and (4) animals generally.

Report of proceedings under the diseases of animals acts for the year 1914 (Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1914, pp. 79).—This is the usual report (E. S. R., 32, p. 778), dealing with the occurrence of infectious diseases of domestic animals, and giving statistical data, etc.

Report on operations of the veterinary sanitary service of Paris and the Department of the Seine during the years 1913 and 1914, H. MARTEL (Rap. Opér. Serv. Vet. Sanit. Paris et Dept. Seine, 1913; 1914, pp. 167, figs. 21).—These are the usual reports (E. S. R., 29, p. 880), giving detailed accounts of the work of the years 1913 and 1914.

The poisonous character of rose chafers, J. M. Bates (Science, n. ser., 43 (1916), No. 1102, pp. 209, 210).—The author records a serious loss among brook trout of Pine Creek, at Long Pine, Nebr., apparently due to feeding on rose chafers, which feed on and sometimes strip bare willows (Salix fluviatilis) that overhang the stream.

The significance of optimal culture media in testing disinfectants, K. Süpple and A. Dengler (Arch. Hyg., 85 (1916), No. 4, pp. 189-197).—The optimal media for obtaining an after-culture of staphylococci was found to be a 3 per cent glucose bouillon. For anthrax spores a 3 per cent glucose bouillon with the addition of 5 per cent horse or cattle serum yielded the most satisfactory results.

Antiphenol serum, Janina Wiszniewska (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 20, pp. 609-612).—The author has isolated a substance from the products of intestinal putrefaction of protein which gives all the characteristic tests with phenolic reagents but which could not be identified as any known phenol derivative. The product is strongly alkaline and possesses some of the general characteristics of the leucomains. It is thermostable. When administered to animals with food it produced definite and characteristic sclerotic lesions of the arteries. When injected intravenously into a horse an antibody was produced which was employed as a therapeutic agent.

On the acetylene gas treatment in ringworm, sarcoptic, symbiotic, and dermatodectic manges, R. Stokoe (Vet. Rec., 28 (1915), No. 1433, pp. 279, 280).—The author has found that powdered calcium carbid applied to the affected part (which has been moistened following a thorough scrubbing) and allowed to effervesce from a minute to a minute and a half, will destroy the ringworm parasite. Carbid can also be used with success in destroying mange parasites.

On the refractive index of the serum in a guinea-chicken hybrid, R. Pearl and J. W. Gowen (*Proc. Soc. Expt. Biol. and Med., 12 (1914), No. 2, p. 48; abs. in Maine Sta. Bul. 245 (1915), pp. 292, 293).*—In connection with some biochemical studies on heredity at the Maine Experiment Station it was observed in a guinea-chicken hybrid, produced from the mating of Cornish Indian Game and guinea fowl, that "there is a definite, characteristic, and permanent difference between the refractive index of the serum of the fowl and that of the guinea; and that in the hybrid the guinea parent is dominant in respect of the physicochemical constitution of the blood as measured by the refractive index."

The origin of the antibodies of the lymph, F. C. Becht and A. B. Luckhard (Amer. Jour. Physiol., 40 (1916), No. 2, pp. 366-371, figs. 3).—"The concentration of antibodies is greater in the serum than in the thoracic lymph, and greater in the thoracic lymph than in the neck lymph, not only in the actively immune animal but also in the passively immune animal; not only after equilibrium is established but at the time when active exchange is occurring. The source of the antibodies of the lymph is the blood by direct exchange

from that fluid. There is no evidence that antibodies originate from the tissues and are emptied into the lymph stream at the seat of formation."

Researches on anaphylaxis produced by diglycylglycin, E. Zuntz and Mile. Diakonoff (Biochem. Jour., 10 (1916), No. 1, pp. 160-168).—Anaphylaxis was produced by the injection of diglycylglycin into rabbits repeated at intervals of seven days. Three injections were occasionally sufficient to produce this effect, but a greater number were preferable for producing clear and definite results. The typical symptons of anaphylactic shock, viz, fall of arterial pressure, increased respiration, and increased peristaltic action, were produced by these injections. A fall in the arterial pressure of more than 2 cm. of mercury was considered as an indication of anaphylactic shock. The intravenous injection of the peptid into a normal animal led to no effect on the normal respiratory rhythm.

The diglycylglycin also displayed some action on the coagulation of the blood. A study of the coagulability of the blood, however, did not serve as a criterion for determining anaphylactic shock in animals previously prepared by the subcutaneous injections of the peptid.

Remarks on the nature and significance of the so-called "infective granules" of protozoa, E. A. Minchin (Ann. Inst. Pasteur, 29 (1915), No. 11, pp. 537-544, figs. 2).—"This brief note does not bring forward any facts hitherto unknown, but attempts to compare and coordinate certain known facts with a view to demonstrate their essential similarity and homology. The conclusion reached is that the phrase 'infective granule' is misleading and erroneous, since the bodies so termed are true endogenous chromidial buds. Consequently the term 'granule-formation' should be replaced by 'endogenous bud formation' and the term 'granule shedding' by extrusion of buds or some similar phrase."

On the action of cholera virus in the immune animal organism, O. Ban (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1916), No. 4, pp. 396-410).— It has been shown that the union of cholera immune serum with the virus of the cholera vibrio in its various forms is not a permanent one, but that a cleavage takes place by which, on the one hand, serum-immune bodies are formed, as indicated by the earlier investigations of Pfeiffer, Friedberger, and Bail, and at the same time cholera virus is liberated which can be demonstrated either by complement fixation or animal inoculation. To this liberation of cholera virus is attributed the weak antitoxic action of anticholera sera. The necessity of the preparation of a serum which will permanently bind the cholera virus (endotoxin) is indicated.

[Foot-and-mouth disease], L. Hoffmann (Bekämpfung der Maulund Klauenseuche durch Heilung der kranken Tiere, I and II; Sichere und rasche Bekämpfung und Vertilgung der an sich harmlosen Maul- und Klauenseuche, III; Heilung der Kranken und Vertilgung der Maul- und Klauenseuche nach meinem System, IV. Stuttgart: Stähle & Friedel, 1912, Nos. 1, pp. VIII+100, pl. 1, figs. 2; 2, pp. XVI+101-292, figs. 49; 1914, Nos. 3, pp. 293-408, pl. 1, figs. 4; 4, pp. 409-502).—The first two parts of this work deal with the combat of foot-and-mouth disease through the curing of affected animals; part 3 with the control of the disease; and part 4 with the cure and eradication of the disease by the author's method.

[Poliomyelitis: Its possible occurrence in the lower animals and the relation of insects to its transmission] (Ann. Rpt. Bd. Health Mass., 45 (1914), pp. 535-601. pl. 1).—Several papers here presented include the following: Further Experiments in Poliomyelitis, by M. J. Rosenau (pp. 535-557), in continuation of those previously noted (E. S. R., 28, p. 160), which reports transmission experiments with the stable fly (Stomoxys calcitrans), largely in tabular form; Experiments to Determine If Paralyzed Domestic Animals and Those Associated

with Cases of Infantile Paralysis May Transmit This Disease, by C. Ten Broeck (pp. 558-577); and A Study of an Epidemic of Infantile Paralysis (Acute Epidemic Poliomyelitis) Occurring in the Southern Connecticut Valley District from November 1, 1911, to November 1, 1912, by J. V. W. Boyd (pp. 578-601), in which is given a brief account of a contemporary animal sickness among horses and an epidemic of paralysis among birds.

The experiments reported by Rosenau, carried on in 1912 and 1913, failed to corroborate the earlier experiments and give no evidence that the stable fly transmits infantile paralysis. In the experiments by Ten Broeck 48 animals were received and the material from 30 of these, including 4 rats, 7 fowls, 9 cats, 3 horses, 4 swine, 1 dog, and 2 cows, was injected into monkeys, but in no case did the monkeys inoculated show any signs of a paralysis or symptoms which would indicate that they were infected with poliomyelitis.

Present views in respect to modes and periods of infection in tuberculosis, M. P. RAVENEL (Jour. Amer. Med. Assoc., 66 (1916), No. 9, pp. 613-618).—"The evidence at hand indicates that in the majority of cases the respiratory tract is the route of infection in tuberculosis. The alimentary tract is a frequent portal of entry for the tubercle bacillus. The tubercle bacillus is able to pass through the intact mucous membrane of the alimentary tract without producing a lesion at the point of entrance. This takes place most readily during the digestion of fats. The bacilli pass with the chyle through the lacteals and thoracic duct into the blood, which conveys them to the lungs, where they are retained largely by the filtering action of the tissues. Infection through the alimentary tract is especially frequent in children.

"Infancy and childhood are preeminently the periods of life when the individual is susceptible to tuberculous infection, and the majority of cases of infection occur during these early years. Any campaign against tuberculosis which leaves out of consideration the protection of children against infection will fail of success. Tuberculous infection in adult life occurs, but not so frequently or readily as generally believed. Tuberculous infection may occur at any age."

Experimental investigations on the determination of the smallest number of bacilli which will produce tuberculosis in the guinea pig; first communication, I. Thöni and A. C. Thaysen (Centbl. Bakt. [etc.], 1. Abt., Orig., 77 (1916), No. 4, pp. 308-319).—The authors were unable to confirm the findings of earlier investigators that so small a number as from 10 to 20 bacilli were sufficient to initiate the disease in the guinea pig. In one test series of 19 animals in which a highly virulent culture in doses of from 10 to 76 bacilli was used it was possible to establish a tuberculosis infection in only one animal after a period of 41 days. In a second series of 22 animals inoculated with doses of from 99 to 343 bacilli the results were entirely negative.

The technique for counting the number of micro-organisms used was the India-ink staining procedure of Burri.

The tubercle bacillus and arsenic, Charpentier (Ann. Inst. Pasteur, 29 (1915), No. 9, pp. 443-458).—In the investigation it was demonstrated that an active growth of the tubercle bacillus took place in a bouillon containing sodium arsenate or atoxyl. The growth was less active in the presence of sodium methyl arsenate and difficult in the presence of sodium cacodylate. The organisms absorbed arsenic from solutions of sodium arsenate and atoxyl. The virulence of the organisms was not changed by such treatment, since they produced an active infection when injected into guinea pigs. It is indicated that the presence of the arsenic in the bacilli probably increases their resistance to destructive agencies. Similar results were obtained with other organisms, viz, Aspergillus, Bacillus coli, B. subtilis, and yeasts. Injections of so-

dium cacodylate did not modify the course of an infection in guinea pigs which had been previously initiated by inoculation of virulent organisms, although the treatment was begun at once.

Clinical observations on coccidiosis in cattle and carabaos, C. H. SCHULTZ (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 2, pp. 115-134).—This paper relates to studies accounts of which have been previously noted (E. S. R., 35, p. 76).

Contributions on ox warbles (Mitt. Ausschusses Bekämpf. Dasselplage, 1912, Nos. 1, pp. 28; 2, pp. 16, pls. 4; 3, pp. 37, figs. 10; 4, pp. 26, fig. 1: 1913, No. 5, pp. 39, pls. 4, figs. 2; 1914, No. 6, pp. 31).—These several contributions relating to ox warbles are as follows: (1) Ox Warble Injury and the Removal of Ox Warbles, by R. Krause; (2) Ox Warble Flies, by H. Gläser; (3) Investigations of Hypoderma Larvæ, by Peter, Ox Warble Removal, by Schöttler, and Warble Flies: The Egg and Oviposition of the Large Warble Fly (Hypoderma bovis), by H. Glüser, previously noted (E. S. R., 29, p. 761); (4) Warble Flies: Observations on the Life History of the Large Warble Fly (H. bovis) and Rearing Experiments, by H. Gläser, previously noted (E. S. R., 29, p. 761); (5) Warble Flies: New Investigations of the Life History of Both Ox Warble Flies, by H. Gläser; and (6) Warble Removal Experiments in the Neuhaus an-der-Oste District in April, 1913 (pp. 3-16), and Warble Removal in Oldenburg in 1913 (pp. 17-25), by Schöttler and H. Glüser, and Experiments Which Show That the Warble Larvæ Cause a Loss of Flesh of Cattle, by H, Gläser (pp. 26-31).

Bacteria in the intestinal tract of calves, H. KÜTHE (Centbl. Bakt. [etc.], 1. Abt., Orig., 76 (1915), No. 6, pp. 409-434, figs. 10; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915). No. 11, pp. 1500, 1501).—The author finds three forms to be constantly present in the intestinal tract of suckling calves, namely, Bacillus acidophilus polymorphus, B. coli, and B. mesentericus.

An extensive bibliography relating to the subject is included.

Hog cholera and its prevention, R. R. BIRCH (Cornell Vet., 6 (1916), No. 2, pp. 90-111, pls. 11).—This article discusses the subject of hog cholera in general, the preparation of serum at the New York State Veterinary College, serum treatment, and the use of serum in the field.

Hog cholera in Cuba, B. M. Bolton (Estac. Expt. Agron. Cuba Bol. 26 (1915), pp. 22).—A general account of "Pintadilla" or hog cholera and preventive measures.

Poisoning by Lathyrus sativus, Szczepanski (Abs. in Vet. Rec., 27 (1915), No. 1392, p. 478).—A report upon the poisoning of two horses by L. sativus present in oats and peas with which they were fed. The feeding of the peas was stopped at once upon discovery of the cause but nevertheless two weeks later all the other horses in the stable, of which there were ten, developed toxic symptoms. Two horses are said to have died from the poisoning.

Contagious abortion in mares, G. Somenzi (Clin. Vet. [Milan], Rass. Pol. Sanit. e 1g., 38 (1915), No. 5, pp. 206, 207; abs. in Vet. Rec., 27 (1915), No. 1399, p. 565).—A report of two outbreaks of this disease in which a bacillus belonging to the paratyphoid B group was isolated at the Milan Station for Infectious Diseases.

Arsenical preparations in the treatment of equine pectoral influenza, Reimers (Berlin. Tierärztl. Wehnschr., 31 (1915), No. 37, pp. 433-436; abs. in Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 39 (1916), No. 1, p. 14; Vet. Rec., 28 (1916), No. 1443, p. 400).—Of 83 cases treated with neosalvarsan, some of which were seriously affected, but one succumbed during treatment and in this case the treatment was commenced too late. The neosalvarsan was used in doses

of 4.5 and of 3 gm., which were mixed respectively with 120 gm. and with 100 gm. of a sterile 0.4 per cent solution of sodium chlorid and administered by intraveneous injection. No abnormal lesions were observed to have been caused by the injection. Other similar preparations, including atoxyl, plasmarsin, and arsinosolvin, did not give as good results. It is concluded that neosalvarsan is the best remedy for pectoral influenza and that it gives 100 per cent of recoveries when used in time.

Epitheliosis infectiosa avium. Contagious epithelioma. Chicken pox. Diptheria. Roup. Canker, O. V. Brumley and J. H. Snook (Vet. Alumni Quart. [Ohio State Univ.], 3 (1916), No. 3, pp. 81-98).—The authors' bacteriological experiments and the satisfactory results obtained from vaccination led them to conclude that they have been dealing with a single disease. The confusion in names has led them to designate the affection as infectious epitheliosis of birds (epitheliosis infectiosa avium).

"Work extending over a period of six years convinces us that typical infectious epitheliosis is due to a combination of two factors: (a) A filterable virus; (b) secondary invading organisms which vary in kind but of which the so-called *Bacillus diphtheriæ columbarum* of Loefler appears to be the most important. The filterable virus is the necessary primary invader which lowers the bird's resistance and thus prepares the tissues for the invasion by the secondary organisms. Neither factor alone will cause the typical disease.

"The excellent results derived from the use of a vaccine made from the secondary organisms, both in prevention and treatment, are due to controlling the secondary infections which cause the serious complications. If these are controlled infection due to the primary virus is mild and soon disappears. (There is a remote possibility that the filterable virus is contained in the vaccine. We have no evidence that this is or is not the case. The presence of the virus in the vaccine would indicate its growth with the other organisms on the cultures. This would be contrary to our present knowledge of filterable viruses. This point will be investigated.)

"The therapeutic dose, as indicated by the large number of birds treated, is 1 cc. for the average adult bird. Younger and smaller birds receive a lesser amount. The immunizing dose found most satisfactory is 1 cc. No bad results have followed when larger doses have been administered. Reports received to date indicate that vaccination is equally efficacious in the treatment of infectious epitheliosis in turkeys."

Spontaneous and experimental leukemia of the fowl, H. C. Schmeisser (Jour. Expt. Med., 22 (1915), No. 6, pp. 820-838).—"The spontaneous occurrence of myeloid leukemia of the fowl is confirmed. Myeloid leukemia of the fowl is transmissible by intravenous or intraperitoneal injection of an organic emulsion.

A report upon an outbreak of fowl typhoid, W. J. TAYLOB (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 1, pp. 35-49).—This is a report of investigations of fowl typhoid during the course of an outbreak in California which led to the following conclusions:

"Fowl typhoid is a specific disease of fowls caused by *Bacterium sanguinarium* occurring sporadically and causing heavy losses among affected flocks, and unless properly investigated may easily be mistaken for fowl cholera because of its high mortality. The specific morbid conditions consist of an enlarged liver containing necrotic areas, an enlarged spleen, and a general anemic condition of the serous and mucous membranes, together with a marked increase in leucocytes and a corresponding decrease of the red cell content of the blood. The increase in leucocytes seems to be confined to the polymorphonuclear variety. Fat, well-conditioned adult fowls are more susceptible than young, nearly mature growing birds.

"Birds may contract the disease by the ingestion of pure cultures of *B. sanguinarium*. Birds fed upon the offal of other birds dead of this disease show a mild nonfatal form of the disease tending to recovery. There is evidence that recovery from this mild form produces more or less of an immunity. Further investigation upon this point is needed.

"The power of some of the red corpuscles of the affected fowls to take the violet stain when the blood is diluted in Toisson's fluid is especially noticeable in this disease. While the lesions produced in fowls which are infected with *B. sanguinarium* resemble in many respects those produced by *B. pullorum*, and although there is a still closer resemblance in the biological characters of the two organisms, there is enough difference to warrant the conclusion that they are distinctly different diseases."

The rearing of turkeys with special reference to the blackhead disease, P. B. Hadley (R. I. State Col. Ext. Bul. 2, n. ser. (1916), pp. 20, figs. 2).—A general discussion of the subject in which is pointed out the importance of controlling by suitable methods of feeding the development of parasites in the intestinal canal and of preventing the invasion of the tissues.

Diseases of poultry, W. Chenevard (Maladies des Volailles. Paris: J. B. Baillière & Sons, 1916, pp. 90, figs. 27).—A small handbook.

RURAL ENGINEERING.

Fourteenth annual report of the Reclamation Service, 1914–15 (U. S. House Representatives, 64th Cong., 1st Sess., Doc. 38, pp. VII+521).—This report relates in particular to work completed and in progress during the fiscal year ended June 30, 1915, but contains also information in regard to previous operations to show the methods, progress, and results of reclamation work.

Classification of expenditures for irrigation work, F. H. Newell (Engin. and Contract., 45 (1916), No. 9, pp. 201-204).—Expenditures for operation and maintenance of irrigation systems are classified and discussed under five general heads, as, (1) development, (2) carriage, (3) distribution, (4) drainage and flood protection, and (5) structure depreciation. Ways of obtaining efficiency and economy in recording and classifying expenditures on such a basis are pointed out.

Irrigation districts in California, 1887–1915, F. Adams (Cal. Dept. Engin. Bul. 2 (1916), pp. 151, pls. 15).—This report is based on data gathered from time to time during the past 15 years in cooperation with the U. S. Department of Agriculture. Its main divisions deal with the original Wright Act of 1887, the irrigation district act of 1897, irrigation district legislation since the act of 1897, the status of California districts July 1, 1915, and court decisions affecting California irrigation districts. Appendixes are included giving (1) a statistical list of California irrigation districts organized under the Wright Act, (2) a list of irrigation districts proposed under that act for which organization was not completed, (3) a list of irrigation district cases affecting California irrigation districts and subjects dealt with in decisions, and (4) an outline of the California irrigation district act of 1897 as amended to 1915.

Water resources of Illinois, A. H. Horton (Springfield, Ill.: Rivers and Lakes Com., 1914, pp. VIII+400, pls. 20, flg. 1).—This report, prepared in cooperation with the U. S. Geological Survey, contains data on stream flow, precipitation, evaporation, drainage, and undeveloped water power and water storage in Illinois. It includes stream profiles, rainfall records, and maps prepared by the Weather Bureau of the U. S. Department of Agriculture; a gazetteer of Illinois streams; and an appendix, by G. B. Hills, on developed water power and drainage districts of Illinois.

Report on Pit River basin, E. G. Hopson and O. W. Peterson (Cal. Cooper. Work, Dept. Int. U. S. Reclamation Serv., 1915, Apr., pp. 140, pls. 19).—This report deals with investigations made in 1914 and 1915 by the U. S. Reclamation Service and the State of California, acting in cooperation, of run-off, storage possibilities, lands, irrigable areas, present uses of water, and power development possibilities of an area including 6,000 square miles in northeastern California which consists of both mountainous and plateau country.

Among the conclusions from this investigation are that in the Pit River basin there are about 180,000 acres of potentially fertile, irrigable land, of which about 40 per cent is now fully or partially irrigated. Of the areas now irrigated only an insignificant proportion is well developed agriculturally, due in large part to unregulated water supplies and to unsatisfactory drainage conditions. Lands in Fall River Valley can be advantageously irrigated by pumping, the supply being practically inexhaustible, while lands adjacent to and in the vicinity of Hat Creek, that are not yet irrigated, can be readily irrigated by direct diversion without storage. Irrigation development in the Pit River basin will not seriously interfere with future power development in or below the basin, or with the navigability of the river. Floods in the Sacramento Valley can not be controlled by storage in the Pit River basin.

Silver Lake project: Irrigation and drainage, J. T. Whistler and J. H. Lewis (*Oreg. Cooper. Work. Dept. Int. U. S. Reclamation Serv.*, 1915, Oct., pp. 179, pls. 27).—This report, prepared in cooperation with the State of Oregon, deals with the irrigation and water-power possibilities of the Silver Lake region, Lake County, Oreg., together with the reclamation of Silver Lake and Paulina Marsh by drainage and pumping.

"The features to which this report has special reference are: (1) The irrigation of lands about Silver Lake and Fort Rock by storage of about 60.000 acre-feet of water at Thompson Valley, into which diversion canals from Sycan River and Long and Coyote creeks will divert the spring run-off from these streams... (2) The reclamation and irrigation of about 9,000 acres of Paulina Marsh by storage on lower Buck Creek at the Emory reservoir site and a drainage canal through the marsh to Silver Lake . . . (3) The possible development of summer power on Silver Creek from Thompson Valley storage for use in pumping to reclaim part of Silver Lake bed; in pumping from ground water to supply additional lands in Fort Rock Valley; and in pumping from Ana River Springs for the irrigation of about 20,000 acres of land in Summer Lake Valley...

"Conditions for the development of the proposed project to irrigate 48,600 acres are exceptionally favorable to development by stages. . . .

"Considerations of available water supply, extent of irrigable lands, and possibilities of irrigation by economic use of water, together with careful cultivation of land and distribution by rotation, have led to adopting for the proposed project a water duty of 1 acre-foot delivered per acre of irrigable land.

"The soils over the larger portion of the project appear to be those of old lake beds and terraces. They are generally free working loams that readily mulch, yet with fine enough material in the subsoils to have good water retaining capacities. Chemical analyses show them to be reasonably fertile in phosphorus and potash and to have medium nitrogen content. The alkali content is comparatively small."

It is estimated that the mean run-off for lower Silver Creek for the past 12 years is 40,400 acre-feet.

Irrigation experiments, G. K. Kelkar (Dept. Agr. Bombay, Ann. Rpt. Expt. Work Surat Agr. Sta., 1913-14, pp. 36-38).—In irrigation experiments with

cotton, sorghum, and tur (pigeon peas), the irrigated plats showed superiority in yield over nonirrigated plats in a dry year, but the irrigation did not "financially show any benefit from the economic standpoint."

Venturi meter developed for accurate measurement of irrigation water, A. A. Wood (Engin. Rec., 73 (1916), No. 13, pp. 411-413, figs. 3).—A recording device, applying the Venturi meter principle, is described which is designed to establish rates on an equitable basis for water users. It is thought that by its use the flat-rate system of charges may be eliminated.

Swamp-land drainage with special reference to Minnesota, B. Palmer (Univ. Minn., Studies Soc. Sci., No. 5 (1915), pp. 138).—This report contains a brief statement relative to the drainage work in foreign countries, the extent of land needing drainage in the United States, drainage laws and development of drainage legislation in Minnesota, drainage procedure, and the extent of swamp-land reclamation in Minnesota. As an appendix is given the drainage statutes of various States and references to drainage cases in the Minnesota Supreme Court. A statistical table showing the land in need of drainage, the area drained, and the cost and average net profit per acre as result of drainage, together with a brief bibliography, is included.

Land bedding as a method of drainage in the Gulf coast region of Texas, E. W. Gruss (Agr. and Mech. Col. Tex. Ext. Serv. Bul. B-11 (1915), pp. 6).—This method is briefly described.

Tile drainage by day labor and by the rod (*Engin. News*, 75 (1916), No. 10, pp. 450-452. figs. 5).—This article describes a land drainage system on the Mississippi River built for three landowners jointly, the work being done by day labor under the direction of the engineer.

Experiments with the automatic water finder in the trap region of western India, H. H. Mann (Dept. Agr. Bombay Bul. 72 (1915), pp. 17, pls. 3).—The results of the experience of others along this line are noted and tests are reported of a so-called automatic water finder.

This finder consists of a wooden case divided into two chambers, the lower containing coils of wire wound on a bobbin, and the upper, at the center, a pivot on which rests a light magnetic needle, which, by its movements, is supposed to detect underground streams. With the instrument are provided a tripod stand and a table on which the instrument is to be placed while taking an observation. On the table there is a white line which is always to be directed toward the magnetic north while using the instrument. "It is obvious that what the instrument detects is not the stream of water, but some electric condition which accompanies that stream."

The results of a large number of tests at different places indicated that "where a stream of water is known to exist the indications of the instrument are by no means constant and the deflection of the needle may vary in direction as well as in amount."

. . . It would seem, however, sufficiently proved that under the conditions which prevail in the trap areas of western India, where underground water occurs in well-defined streams flowing in rock fissures, sometimes under little or no pressure and sometimes under considerable pressure, the automatic water finder can be used with advantage in locating streams of water which can be tapped either by well digging or by boring."

The conditions affecting the accuracy of the instrument and the precautions to be observed in its use are explained.

Investigation of the pollution and sanitary conditions of the Potomac watershed, H. S. Cumming et al. (Pub. Health Serv. U. S., Hyg. Lab. Bul. 104 (1916), pp. 231, pls. 50).—This report is the result of an investigation of the pollution of the Potomac River and its tributaries begun June 2, 1913, and

continued until May 31, 1914. The investigation included a sanitary survey of the Potomac River watershed and laboratory studies of the water, mud, plankton, and shellfish. The sanitary survey included investigations as to the number of persons on the watershed, the prevalence and distribution of typhoid fever, the water supplies, sewage-disposal systems, and character and amounts of trade wastes.

It was found "that at no point above Washington is the water of the Potomac River safe for use as a public water supply without reasonable treatment. . . . At no time was the condition over and about the Washington sewer outlet such as to constitute a nuisance. Even during the period of lowest stream flow and highest temperature the river in the area of heaviest pollution . . . has at all times sufficient oxygen available for the sewage now discharged into the river and enough to take care of the sewage which will probably be added for several years to come. In addition to the dissolved oxygen contained in the water of the river as it flows from the Great Falls, the great areas of flats on each side of the river for many miles act as oxygen generators. The amount of oxygen given off, depending in part upon the condition of plant life, turbidity, and sunshine, is, therefore, greatest during the summer when there is the most need for it. In addition to releasing enormous volumes of oxygen these flats are breeding places for plankton forms, which themselves materially assist by biological processes in the breaking down of sewage and the consequent purification of the river. . . . Few intestinal organisms from above reach Maryland Point, and these disappear in the stretch of 10 miles between that point and Popes Creek, at which section evidence of pollution from the upper river has disappeared.

"In an examination of oysters from all the beds in the whole river and its tributaries, extending over an entire season, no dangerously polluted oysters were found in the Potomac River proper. . . Analysis of the results obtained during the year in the examination of shellfish and of water taken from over the oyster beds shows that the periods of highest *Bacillus coli* count in the two were not coincident." . . .

Tests of bacteriological methods are also reported in some detail. As a result of these studies it is recommended that the lactose bile presumptive test be not used, because of the unreliable results obtained therefrom; and that the use of lactose broth fermentation tubes, with confirmation on endo medium, be adopted as a routine procedure in the examination of water and shellfish for the determination of the presence of *B. coli*.

Analyses of waters, J. C. Beunnich (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1914–15, pp. 50–52).—Analyses of 65 samples of Queensland waters are reported and discussed with reference to their use for domestic, stock-watering, and irrigation purposes.

Results of first year's experiments with small sewage treatment plants by U. S. Public Health Service, L. C. Frank (Engin. and Contract., 45 (1916), No. 18, pp. 420-422).—The results of experiments with the Imhoff tank and sand bed combination for use on a small scale are reported, from which the following conclusions are drawn:

"It is possible by means of a five-hour mean detention period in a properly designed Imhoff tank to remove from the raw sewage of small communities 98 per cent of the settleable solids without producing a nuisance. A mean detention period of six hours, based on the average daily flow, will not cause the sewage to become septic or foul smelling if it is fresh when it enters the tank. The accumulation of a disagreeable mass of grease and fecal matters in the first compartment of the settling chamber may be prevented by the introduction of a horizontal coarse mesh screen at the water level of this chamber. The screen

keeps the floating matters submerged and apparently results in all fecal matter sooner or later becoming water-logged and sinking through the slot into the sludge chamber. It is too soon to state with conviction the amount of digested sludge that may be expected from small-scale tanks, but one tank indicates an apparent accumulation of 2.6 cu. ft. per year per person and another tank 4 cu. ft. The only period during which the Imhoff tanks required daily attention was the foaming period, which lasted about ten days, and during which time some of the foam had to be removed and buried. At all other times attention once a month at the most was ample. Since the foaming period has been passed the scum formation has been slight.

"The decomposed sludge obtained from the small-scale Imhoff tanks resembled that obtained in large tanks except that it had a much higher moisture content. This may perhaps be explained by the shallowness of the sludge layer. A 15-in, sand bed dosed with settled sewage at a net rate of 190,000 gal. per acre per day during the second summer reduced an average oxygen demand of 63 parts per million to 12 parts per million (24 hours, 20° C.). This is probably ample purification for many cases, but insufficient for others. The sand bed required very little attention during the summer months, but what would seem to be a prohibitive amount of attention during the winter months, even though covered with a tongue-and-groove wooden cover. No nuisance was produced during the summer months by the dosing of the uncovered sand bed with the Imhoff tank effluent. The growth of weeds on the sand surface did not seem to have an unfavorable effect upon the operation of the sand bed."

A practical process for the sterilization and utilization of polluted water in the field, Rolland (Jour. Pharm. et Chim., 7. ser., 12 (1915), No. 6, pp. 179–182, flg. 1; abs. in Chem. Abs., 10 (1916), No. 2, p. 236).—Water in a barrel is treated with a sufficient excess of calcium hypochlorite of known strength to impart a distinct chlorin taste. It is next passed into a large funnel containing absorbent cotton, and then upon a perforated disk with alternate layers of finely powdered charcoal, fine sand, powdered charcoal, coarse sand, wood charcoal, crushed stone, and straw to distribute the water.

Dams and weirs, W. G. Bligh (Chicago: Amer. Tech. Soc., 1915, pp. [VIII]+206, figs. 124).—This is an analytical and practical treatise on gravity dams and weirs, arch and buttress dams, and submerged weirs and barrages. It contains the following chapters: Gravity dams, design of dams, unusually high dams, notable existing dams, special foundations, gravity overfall dams or weirs, arched dams, multiple arch or hollow arch buttress dams, hollow slab buttress dams, submerged weirs founded on sand, and open dams or barrages.

Good roads of Monroe County, New York, 1915, J. Y. McCLINTOCK (Rochester, N. Y.: Co. Supt. Highways, 1915, pp. 48, pl. 1, figs. 86).—This is a report of the county superintendent of highways for 1915, giving tabulated statements of expenditures for highway purposes during the year and calling attention to the more important features of the work.

Fourteenth annual report of the state board of public roads of the State of Rhode Island (Ann. Rpt. Bd. Pub. Roads R. I., 14 (1916), pp. 60).—This is a report of expenditures on road and bridge work in the State for 1915.

Surface oiling of earth roads, B. H. PIEPMEIER (Ill. Highway Dept. Bul. 11 (1915), pp. 28, figs. 26; Sci. Amer. Sup., 81 (1916), No. 2102, pp. 250, 251).—"It is the purpose of this publication to present as many facts concerning the use of oil as it is possible to secure at this time, also to describe what is shown by experience to be the best method of preparing the road and applying the oil, together with a few suggestions that may be of some assistance to the contractor or individual who has such work under consideration.

"Roads should not be oiled until they have a permanently established grade. . . . Low, flat, undrained roads should not be oiled until proper drainage has been attended to. . . . Roads that have a preponderance of heavy hauling should not be selected for oiling. . . . The main purpose of oiling earth roads is to suppress the dust and aid in maintaining a smooth and waterproof surface. . . .

"It is very important that the road surface be oiled when it is smooth, free from dust, and in a condition to absorb the oil. . . . Best results may be expected when the road is reasonably dry for about 2 in. on the surface. . . . The oil should be applied at the rate of from $\frac{1}{4}$ to $\frac{1}{2}$ gal. per square yard of surface. If the road has never been oiled, or if more than a season has elapsed since a previous oiling . . . about $\frac{1}{2}$ gal. per square yard will be required. If the road or street has been oiled regularly, from $\frac{1}{4}$ to $\frac{1}{3}$ gal. per square yard will usually be satisfactory. . . . After a road has been oiled for several years, one light application each year may be sufficient, or at least equal in results to two applications per year on a new oiled road. . . .

"The uniform distribution of the material is one of the essential requirements for success. . . . Better results can be secured from sanding the road slightly after either hot or cold oil has been applied. . . . A hot oil application should be followed with a light dressing of sand . . . at a rate of 1 cu, yd. to each 100 to 150 sq. yds. of road surface. . . . It seems essential that careful analysis be made of all road oils before using and that preference be given to the natural and semiasphaltic products over the parafin oils."

Other general information regarding the oiling of sand and gravel and macadam roads is given.

Popular handbook for cement and concrete users, M. H. Lewis and A. H. Chandler (New York: The Norman W. Henley Publishing Co., 1911, pp. IX+430, figs. 126).—This is a comprehensive and popular treatise on the principles involved and the methods employed in the design and construction of modern concrete work, covering both plain and reinforced concrete.

It contains the following chapters: Kinds of cement and how they are made; properties, testing, and requirements of hydraulic cements; concrete and its properties; sand, broken stone, and gravel for concrete; how to proportion the materials; how to mix and place concrete; forms for concrete construction; the architectural and artistic possibilities of concrete; concrete residences; mortars, plasters, and stuccos and how to use them; the artistic treatment of concrete surfaces; concrete building blocks; the making of ornamental concrete; concrete pipes, fence posts, etc.; essential features and advantages of reinforced concrete; how to design reinforced concrete beams, slabs, and columns; explanation of the theory of the design of reinforced concrete beams and slabs; systems of reinforcement employed; reinforced concrete in factory and general building construction; concrete in foundation work; concrete retaining walls, abutments, and bulkheads; concrete arches and arched bridges; concrete beam and girder bridges; concrete in sewerage and drainage works; concrete tanks, dams, and reservoirs; concrete sidewalks, curbs, and pavements; concrete in railroad construction; the utility of concrete on the farm; the waterproofing of concrete structures; grout or "liquid concrete" and its uses; inspection of concrete work, a summary of essential rules and principles of construction for securing good concrete work; and cost of concrete work.

Concrete on the farm and in the shop, H. C. Campbell (New York: The Norman W. Henley Publishing Co., 1916, pp. 149, figs. 51).—This is a popular treatise on the fundamental principles of concrete construction with particular reference to farm structures. It contains the following chapters: Gen-

eral summary of concrete principles; aggregates; principles of proportioning; mixing concrete; placing concrete; protection after placing; cold weather concreting; recommended mixtures; forms; concreting tools; foundations; principles of reinforcing; materials for reinforcing; walls and fences; posts; rubble concrete; tanks and troughs; cisterns; form removal; hog wallow; manure pit; repairs of leaks in tanks, etc.; hotbeds; roofs for small buildings; pavements, feeding floors, and walks; steps; and well curbs and platforms.

Tests of three large-sized reinforced-concrete slabs under concentrated loading, A. T. Goldbeck and E. B. Smith (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 6, pp. 205-234, pl. 1, figs. 28).—Tests of three large reinforced-concrete slabs to determine their effective widths under concentrated loading, as defined by McCormick (E. S. R., 33, p. 487), and "to demonstrate the application of the theory of narrow rectangular beams to the design of wide slabs supported at two ends and subjected to concentrated loads," are reported All three slabs were 32 ft. wide, of 16 ft. span, and reinforced but not transversely, made of machine-mixed 1:2:4 concrete. A complete description of the slabs is given in the following table:

Description	of	reinforced-concrete	slabs	used	in	tests.
-------------	----	---------------------	-------	------	----	--------

Thickness.		Reinforcing.		Modulus of elasticity.	Central breaking	
Total.	Effective.	Size.	Spacing.	Per cent.	of concrete.	of slab.
Inches.	Inches.	Inches.	Inches. 10.5	0.75	2,900,000	Pounds. 119,000
10	81/2	square). % (plain square).	8.87	.75	4,000,000	80,000
7	ii ii	14 (plain square).	5. 56	.75	3,000,000	40,000

The data of results are graphically reported.

It was found that "with an increase in load the effective width seems to increase slightly. Values for effective width were obtained from the steel deformations as well as from the concrete deformations, but . . . the concrete deformations gave the most conservative widths. . . . As the thickness increases the effective width decreases, varying from 109 per cent of the span length for a 6-in, slab to 75 per cent of the span for a 10.5-in, slab. The least value for effective width shown by these tests is roughly, then, about 0.7 of the span length. . . . It would seem that under extremely heavy loads, requiring very thick slabs, the effective width might be decreased as low, possibly. as 0.6 of the span length. However, 0.7 of the span will always be safe, and in general is a sufficiently conservative figure to use."

The effective widths of the spans tested are given in the following table:

Effective widths of reinforced-concrete slabs, 16-ft. span by 32 ft. wide, for center loading.

Center load.	Slab (10½ in. effective thickness).	Slab (8½ in. effective thickness).	Slab (6 in. effective thick- ness).
Pounds. 15,000 20,000 25,000 32,500 35,000	11.6 ft.=72.3 per cent of span 11.5 ft.=71.9 per cent of span 12.1 ft.=75.7 per cent of span	11.4 ft.=71.6 per cent of span. 13.0 ft.=81.2 per cent of span. 12.9 ft.=81.1 per cent of span. 14.5 ft.=90.7 per cent of span.	12.7 ft.=79.5 per cent of span. 17.5 ft.=109.3 per cent of span.
Safe load	12.1 ft75.7 per cent of span	12.9 ft.=81.1 per cent of span.	17.5 ft. = 109.3 per cent of span.

"The usual rectangular-beam design formulas may be applied to the design of slabs by merely substituting for b its value as determined by these investigations, b=0.7L. The corresponding formulas then become—

For rectangular beams.

(1) $M_o = \frac{1}{2} f_o k j b d^2$.

(2) $M_s = p f_s j b d^2$.

(3) $p = \frac{a_s}{bd}$.

(4) $p = \frac{\frac{1}{2}}{f_o} \left(\frac{f_s}{nf_o} + 1\right)$.

(5) $k = \sqrt{2pn + (pn)^2} - pn$.

For slabs under central concentrated loads. $M_o = \frac{1}{2} f_o k j \frac{7}{10} L d^2$. $M_s = p f_s j \frac{7}{10} L d^2$. $p = \frac{\frac{10a_s}{7Ld}}{7Ld}$. $p = \frac{f_s}{f_o} \left(\frac{f_s}{nf_o} + 1\right)$. $p = \frac{f_s}{f_o} \left(\frac{f_s}{nf_o} + 1\right)$. $k = \sqrt{2pn + (pn)^2} - pn$.

"It is interesting to note that in substituting for M_o and M_s in formulas 1 and 2 their value $\frac{PL}{4}$ the L's cancel, showing that the safe load-carrying capacity of the slab is independent of the span; thus—

1 becomes
$$\frac{PL}{4} = \frac{1}{2} f_0 k j \frac{7}{10} L d^2$$
 or $P = \frac{7}{5} f_0 k j d^2$.
2 becomes $\frac{PL}{4} = p f_s j \frac{7}{10} L d^2$ or $P = p \frac{14}{5} f_s j d^2$.

"The above investigations were made on slabs the width of which was twice the span length, so that the stress at the extreme edges was very small. The conclusions must therefore be applied to such cases only. When the ratio of width of slab to span length is less than 2, these conclusions may or may not apply, and additional investigations are now being made to determine the proper value of effective width to use under such conditions."

The action of Portland cement mortar in different salt solutions, V. Ropt (Mitt. K. Materialprüfungsamt Berlin-Lichterfelde West, 33 (1915), No. 3-4, pp. 229-240).—Tests to determine the influence of solutions of sodium, calcium, and magnesium chlorids and sulphates in concentrations of 0.1, 1, and 10 per cent on Portland cement mixtures with sand, 1:3 and 1:6, when immersed in the solutions for periods as long as six months, showed that none of the solutions except that of calcium sulphate had an injurious effect on the 1:3 mixture. Calcium sulphate, on the other hand, showed evidences of a destructive influence. With the 1:6 mixture only the sulphate solutions had a destructive effect, but this was, however, very marked. The action was very arbitrary and irregular. The chlorids of calcium and magnesium produced an increase in the leaching out of lime from the cement, especially when the salt solutions were concentrated and the cement mixture lean.

Further studies are in progress on the effect of leaching solutions.

Some tests on hydrated lime addition to concrete for road work, E. ASHTON (Engin. and Contract., 45 (1916), No. 9, pp. 206, 207).—Tests are briefly reported in which 5, 10, and 15 per cent by weight of hydrated lime was added to concrete.

The results showed that "no greater freedom of movement of the mass was noticed. As the lime was increased more difficulty was experienced in getting the material into the test forms. . . . With same angle and same percentage of water concrete did not flow more readily by the addition of hydrate of lime.

and as the percentage of hydrate of lime was increased the mass became more sticky and did not flow so readily. By far the most important observation made was that the addition of hydrate of lime did prevent segregation, and so much so as to make this the biggest gain that can be gotten from the use of hydrate of lime."

Experiments on wire rope, M. Rudeloff (Mitt. K. Materialprüfungsamt Berlin-Lichterfelde West, 33 (1915), No. 3-4, pp. 198-209, figs. 10).—Experiments on the strength of four wire ropes gave inconclusive results. Experiments on the durability of three wire ropes containing, respectively, 294, 210, and 294 wires of 0.7, 0.68, and 0.59 sq. mm. cross section and having respective total wire cross sections of 113.1, 76.3, and 80.4 sq. mm. and total diameters of 20, 17, and 17 mm., are also reported. The second rope was found to be the most resistant and the third the least resistant.

Consideration on hauling by animal and mechanical power, F. ACHILLES (Wehnschr. Brau., 32 (1915). Nos. 7, pp. 49–53, figs. 6; 8, pp. 62–64. figs. 2; 9, pp. 88–90, figs. 2).—The results of an investigation into the factors affecting the efficiency and economy of hauling loads by animal power and by motor truck are reported in both tabular and graphic form and analyzed to determine the limits of the efficiency and economy of the two types of power under different conditions.

A final graphic comparison of the cost of hauling by the two kinds of power is made which is based on the cost per ton kilometer and the daily accomplishment in ton kilometers. This comparison shows that up to a daily accomplishment of about 200-ton kilometers animal power hauling one wagon for 100-ton kilometers per day and two wagons for from 100 to about 200 ton kilometers per day is more economical than one motor truck of 2 tons capacity. With a daily accomplishment of from 200 to 700 ton kilometers it is shown that the motor truck alone in varying capacities or a train of motor trucks is more economical than a train of from three to eight wagons drawn by animal power.

An economic study of the farm tractor in the corn belt, A. P. Yerkes and L. M. Church (U. S. Dept. Agr., Farmers' Bul. 719 (1916), pp. 24, fig. 1).—This bulletin reports and discusses data from selected reports from over 200 tractor owners in Illinois whose farms are typical of corn-belt conditions, the data being considered correct for conditions existing in the corn belt in the spring of 1916.

The principal points brought out by the experience of these owners are summarized as follows:

"The chief advantages of the tractor for farm work, in the opinion of the operators, are (1) its ability to do the heavy work and do it rapidly, thus covering the desired acreage within the proper season; (2) the saving of man labor, and the consequent doing away with some hired help; and (3) the ability to plow to a good depth, especially in hot weather. The chief disadvantages are difficulties of efficient operation and the packing of the soil when damp.

"The purchase of a tractor seldom lowers the actual cost of operating a farm, and its purchase must usually be justified by increased returns.

"One of the most important points in connection with the purchase of a tractor is to obtain one of suitable size for the farm on which it is to be used. In this connection experienced tractor owners in Illinois make the following recommendations:

"For farms of 200 crop acres or less, the 3-plow tractor; for farms of from 201 to 450 crop acres, the 4-plow tractor, with the 3-plow outfit second choice; for farms of from 451 to 750 crop acres, the 4-plow tractor, with the 5- and 8-plow outfits tied for second choice; a farm of 140 acres is the smallest upon which the

smallest tractor in common use, the 2-plow outfit, may be expected to prove profitable.

"Medium-priced tractors appear to have proved a profitable investment in a higher percentage of cases than any others.

"The life of tractors, as estimated by their owners, varies from 6 seasons for the two-plow to $10\frac{1}{2}$ seasons for the 6-plow outfits. The number of days a tractor is used each season varies from 49 for the 2-plow to 70 for the 6-plow machines. No definite figures on the repair charges for late model tractors can be given; it would not seem safe, however, to count upon less than 4 per cent of the first cost annually (this representing the average for farm machinery in general).

"Under favorable conditions a 14-inch plow drawn by a tractor covers about 3 acres in an ordinary working day. Under unfavorable conditions large gang plows will cover less ground per day per plow pulled than will the small ones. Two and one-half gal. of gasoline and 0.2 gal. of lubricating oil are ordinarily required in actual practice to plow 1 acre of ground 7 in. deep. The size of the tractor has little influence on these quantities,

"Plows drawn by tractors do somewhat better work, on the whole, than horsedrawn plows. In Illinois the depth plowed by tractors averages about 1.5 in. greater than where horses are used. Efficient operation is essential to success with a tractor, and proficiency usually can be obtained more cheaply and easily by previous study and training than by experimenting with one's own tractor. With a proficient operator the tractor is a very reliable source of power.

"The use of the tractor for custom work is usually an indication that the home farm is not large enough to utilize it economically. The doing of custom work with the tractor, on the whole, appears to be a questionable practice, although nearly 45 per cent of machines are used for such work to some extent.

"A tractor displaces on an average about one-fourth of the horses on the farm where it is used. On a large number of Illinois farms brood mares constituted 33 per cent of the work stock before the purchase of the tractor. The use of the tractor increased this proportion only 3 per cent. . . . Both increases and decreases in the crop yields are reported from the use of the tractor, although favorable effects are more common than unfavorable. However, increases are not sufficiently frequent to warrant a farmer placing much dependence on the tractor in this respect."

The economics of the farm tractor, E. R. WIGGINS (Power Farming, 25 (1916), No. 2, pp. 16, 45, 48, fig. 1; Farm Implements, 30 (1916), No. 2, pp. 58, 60, 62, 62A).—The results of an investigation conducted in Nebraska on tractor costs are reported in detail, three systems of tractor farm management being considered, namely, (1) private ownership, (2) cooperative management, and (3) custom operation.

It is concluded that a study of costs of tractor operation does not entirely indicate the advantages of tractor over horse farming since, while there is a saving in favor of the tractor, the added investment necessary must be considered. "The advantage, however, comes . . . in the added work that can be done with the tractor, at the same cost, and besides all this, the tractor does not use materials that man can use to reduce the cost of living."

The proper bearings for farm tractor uses, C. M. Eason (Farm Machinery, No. 1271 (1916), pp. 26. 27, fig. 1).—This article deals with different types of antifriction bearings, bearing loads, bearings for radial loads only, rollers v. balls, and size and capacity of bearing. Roller bearings are favored for tractors.

Indigenous implements of the Bombay Presidency, G. K. Kelkar (Dept. Agr. Bombay Bul. 66 (1914), pp. VI+100, pls. 26).—This is a general survey of the indigenous implements of the Presidency proper which include plows, harrows, clod crushers, seed drills, interculturing and weeding implements, harvest-

ing implements, threshing appliances, winnowing and cleaning appliances, appliances in the preparation of crops for the market, appliances for transport of agricultural products, implements used in improvement of land, Konkan implements, mallad (a heavy rainfall tract of Karnátak) implements, hand tools, water lifts, and yokes and hitching. Appendixes are included giving a glossary of vernacular words of crops, the kinds of wood used in the manufacture of implements with their scientific names, and vernacular names of different parts of implements with their English equivalents.

Directory and specifications of plows for tractor use (Farm Machinery, No. 1271 (1916), pp. 22, 23).—This list includes 91 of the types manufactured in the United States.

Proper use of rams for farm water supplies, W. G. Kirchoffer (*Engin. News*, 75 (1916), No. 10, pp. 457, 458, figs. 2).—The hydraulics involved in the design of a hydraulic ram system of water supply are briefly presented, together with a specific example.

Concrete silos, E. S. Hanson (Chicago: The Cement Era Publishing Co., 1916. pp. 174, figs. 78; rev. in West. Engin., 7 (1916), No. 2, pp. 78, 79; Engin. News. 75 (1916), No. 7, p. 319).—This book represents an attempt to compile and summarize the present available knowledge of concrete silo construction. It contains the following chapters: Why build a silo? what a good silo should be: how concrete meets the requirements; advantage over other kinds of silos: size and shape of a silo; the different types of concrete silos; the foundation of the silo; the monolithic silo; the Polk system; the Monsco system; the Reichert system; other monolithic systems; the pit silo; the metal lath silo; the concrete stave silo; the concrete block silo; doorways, doors, roofs, etc.; and how to increase the silo business. It is stated that part of the material was drawn from bulletins of the state agricultural experiment stations.

RURAL ECONOMICS.

The agricultural element in the population, E. Merritt (Quart. Pubs. Amer. Statis. Assoc., n. scr., 15 (1916), No. 113, pp. 50-65).—Among the conclusions brought out in this paper, presented at the annual meeting of the American Statistical Association, Washington, D. C., December 29, 1915, are that the principal reasons for the decreasing percentage of the total workers employed in agriculture are that the agricultural element in the population is becoming more efficient, and that in the readjustment or changes in the methods of producing and distributing agricultural products agricultural people now perform a smaller part of the complete operations than was the case formerly. As evidence of the increased efficiency are the facts that the agricultural workers are producing more crops per capita and use a smaller percentage of the total population for the purpose than formerly.

Another indication of the increased efficiency is the fact that the average number of acres of crops cultivated per agricultural worker is increasing and is accompanied by an increased number of horses on farms per agricultural worker and by an increase in the average yields per acre.

The decrease in the agricultural and rural population in the north Central States is due to a decreased number of farms and to smaller farm families.

The author states that anything that tends to upset the relationship between the supply and demand of labor in one field of endeavor sets in motion a migration from one part of the country to another or from one country to another, and that the relationships between the rural and urban population are rendered unstable owing to differences in death rate, birth rate, and migration.

Although the fecundity of married women in rural districts is greater than those of the same nativity in urban districts, the presence of a larger number of foreign born in cities causes the relative birth rates to appear about equal. When the death rate is compared, age for age, it is found to be higher in the urban than in the rural districts, the difference being greatest at those ages at which the largest number of deaths occur. Even if the birth rate for rural and urban districts were the same, the greater death rate in cities results in a smaller percentage of those born in cities reaching the productive age periods. Migration from rural districts apparently begins with those 10 to 15 years of age, and practically ceases at 35 years of age. The higher death rate in cities accounts for the fact that a large percentage of those in rural districts survive.

He also points out that the white females are migrating from rural districts in greater numbers than males, and that their migration begins at an earlier age. The extensive use of agricultural machinery in the United States is probably the cause of this migration from rural districts. As long as the women are employed in the fields they contribute to the farm income. When an agricultural machine is introduced it not only takes away the field work of the farm women so that they become of less economic value on the farm, but it also makes them seek remunerative employment elsewhere.

Information for prospective settlers in Alaska, C. C. Georgeson (Alaska Stas. Circ. 1 (1916), pp. 30, pls. 5).—This circular is based largely on the results of the station's work. It is estimated that in the whole Territory there are about 100,000 square miles which can be made available for tilling and for grazing purposes, but about one-half of this area has little value except for the latter purpose. General information is given concerning the climate, agricultural conditions, how to obtain a farm, chances for work and wages paid, transportation facilities, cost of living, crops and live stock, population, means of communication, etc.

An article by M. D. Snodgrass is included pointing out some of the problems confronting early settlers in the Matanuska Valley. Methods of clearing the land at present are various and crude, including grubbing with mattock and shovel, cutting some of the roots and lining with rope through a lead block, pulling stumps with homemade stump pullers, and burning during the dry seasons. The principal crops in this area are barley, oats, rye, potatoes, cabbage, turnips, rutabagas, carrots, tomatoes, cauliflower, beets, and most of the common garden vegetables. Wild fruits are abundant in this region, consisting of currants, blueberries, salmonberries, raspberries, gooseberries, cranberries, and a number of other edible sorts. The strawberries so common on the coast of southeastern Alaska are not found in the Matanuska country, but wherever planted they grow well.

Under the present homestead laws any person who has not used his homestead rights may take up 320 acres of land (160 acres in the National Forests) and acquire patent thereto by establishing his residence on the land and putting one-eighth of it under cultivation within three years after taking up the land. On the whole, the amount of land allowed is deemed more than the ordinary man can handle and comply with the laws; 160 acres being regarded as sufficient for the average person.

Statistics of the food supply in Germany, R. M. Woodbury (Quart. Pubs. Amer. Statis. Assoc., n. ser., 15 (1916), No. 113, pp. 93-109).—This paper, read at the annual meeting of the American Statistical Association, Washington, D. C., December 29, 1915, is a review of discussions by various authors as to the possibilities of a decision of the European War being brought about by the starvation of Germany. After reviewing the literature the author concludes:

"There is little possibility that Germany can be starved. Her supplies are probably sufficient to cover the minimum practical requirement. Her food supply falls considerably short of the actual rate of consumption in 1912–13, and it must be conserved and carefully distributed to insure a sufficiency in the last months before the new harvests are available. There are distinctly less meat and animal products available than in normal times. The serious danger, it seems to me, is that disaffection may be spread among the working classes by restrictions on the consumption of foodstuffs, and above all by the increase in prices, which may seem to them entirely unnecessary if, as the government has announced, there is really enough food for all."

Settlement or employment on the land in England and Wales of discharged sailors and soldiers (Final Rpt. Dept. Com. Land Settlement Sailors and Soldiers, 1915, pt. 1, pp. 30, pl. 1).—In this report are considered methods of settlement, advisability of ownership and tenancy, selection and training of settlers, and provision for expert guidance and working capital.

The use of agricultural motors and machinery, D. H. Gorría (Mem. R. Acad. Cien y Artes Barcelona, 3. ser., 12 (1915), No. 4, pp. 27).—The author discusses the importance of machinery in the agricultural systems of various countries, its influence upon the relation of food supply to the population, and the relation of the use of machinery to the development of Spanish agriculture.

A farm management demonstration on 161 Chautauqua County farms for the year 1914, H. B. Rogers (Chautauqua Co. [N. Y.] Farm Imp. and Inform. Bur. Bul. 1 (1916), pp. 14, ftg. 1).—This bulletin gives a brief summary of the results obtained in a farm management survey of 161 Chautauqua County farms made in connection with the extension work of the county agricultural agent in 1914.

Marketing and farm credits (Madison, Wis.: Nat. Conf. Marketing and Farm Credits, 1916, pp. IX+531).—This report consists of papers read at the third annual session of The National Conference on Marketing and Farm Credits in joint program with The National Council of Farmers' Cooperative Associations, in Chicago, November 29 to December 2, 1915. It deals with the following subjects: Organizing agricultural cooperation, marketing farm products, standardization of farm products, warehousing and standardization of farm products, local and terminal elevators, rural credit aids to land purchase, present facilities for land purchase and need of legislation, and financing the farm business.

Farmers' market bulletin (North Carolina Sta., Farmers' Market Bul., 3 (1916), No. 16, pp. 32, fig. 1).—This includes the usual list of farm products for sale, and brief discussions of the benefits that may accrue to the cotton farmers through organization in improving their products, establishing uniform grades of cotton, warehousing, and securing credit and better prices for their products. The text of an act passed in 1915 relating to the incorporation, maintenance, and supervision of credit unions and cooperative associations in North Carolina is also given.

Live stock shipping associations (Wallaces' Farmer, 41 (1916), No. 10, p. 425).—This article gives a brief description of a live stock shipping association formed at Farmington, Minn., together with the constitution and by-laws.

A system of accounts for primary grain elevators, J. R. Humphrey and W. H. Kerr (U. S. Dept. Agr. Bul. 362 (1916), pp. 30, pls. 3).—Fifteen forms are given, with a description of their use for a system of accounts with an idea of establishing a uniform system for primary grain elevators. These forms are as follows: (1) Cash, journal, purchase, and sales record; (2) record of grain receipts; (3) record of grain purchases; (4) record of grain shipments and sales; (5) record of hedges; (6) record of sales to arrive; (7) patronage ledger

(for cooperative elevators); (8) grain and merchandise report; (9) manager's report; (10) grain check; (11) scale ticket; (12) storage ticket; (13) sales ticket; (14) cash receipt; and (15) cost analysis.

Agricultural statistics of Saxony, Würzburger (Statis. Jahrb. Königr. Sachsen, 42 (1914-15), pp. 104-129).—This continues information previously noted (E. S. R., 31, p. 96) adding data for 1913-14.

AGRICULTURAL EDUCATION.

Proceedings of the twenty-ninth annual convention of the Association of American Agricultural Colleges and Experiment Stations and of the fourth annual convention of the Land-Grant College Engineering Association, edited by J. L. Hills (Proc. Assoc. Amer. Agr. Cols and Expt. Stas. and Land-Grant Col. Engin. Assoc., 1915, pp. 304).—This is a detailed account of the proceedings, including the papers submitted, of these two conventions held at Berkeley, Cal., August 11–13, 1915 (E. S. R., 33, p. 301).

The proceedings of the convention of the Association of American Agricultural Colleges and Experiment Stations include the Report of the Bibliographer, A. C. True, submitting a list of documents that record the history of agricultural extension legislation, together with a brief summary of the chief factors in bringing it about (pp. 32–44); report of the committee on instruction in agriculture on College Courses for the Preparation of Extension Workers (pp. 45–70); report of the committee on college organization and policy including a discussion of the forms of organization in various land-grant agricultural institutions, tentative outlines of a plan for study of college organization and policy, and a bibliography of college organization and administration (pp. 104–123); report of the committee on experiment station organization and policy dealing with the functions of the stations in relation to various forms of regulatory activity (pp. 123–125); report of the committee on extension organization and policy offering suggestions toward standardization of methods of administration (pp. 125–129); and the following addresses:

Address of Welcome, B. I. Wheeler (pp. 19, 20); The Presidential Address, on A National System of Education, E. A. Bryan (pp. 72-82); An Account of the Methods of Work of the Agricultural Institutions in California, T. F. Hunt (pp. 83-90); The Exhibit in Agricultural Education at the Panama-Pacific International Exposition, A. C. True (pp. 91-94); Economic Science in Agricultural and Mechanical Colleges, C. A. Duniway (pp. 94-96); The Preparation of Teachers as Contemplated in the Nelson Amendment, A. R. Hill (pp. 96-100); Exchange of Instructors in Agricultural College Work, H. L. Russell (pp. 102-104); The Correlation of the College of Agriculture with the Other Colleges of the State, A. Vivian (pp. 130-134); The Place of Mechanic Arts in Land-grant Institutions, R. A. Pearson (pp. 135-140); The Relation of the Bureau of Education to the Agricultural Colleges, S. P. Capen (pp. 140-146); Federal Aid to Engineering Experiment Stations, F. G. Newlands (pp. 146-150); The Preparation Required for the College Teacher in Agriculture, R. A. Pearson (pp. 156-159); The Preparation Required for Research Work in Agriculture, T. F. Hunt (pp. 159-161); The Preparation Required for Extension Work in Agriculture, A. C. True (pp. 161-165); The Administration of Engineering Divisions of Land-grant Colleges, H. J. Waters (pp. 168-171); Duplication in Engineering Between Land-grant Institutions and State Universities, A. Marston (pp. 171-177); The Annual Report, R. H. Forbes (pp. 179-182); Bulletins, H. G. Knight (pp. 182-185); The Publication of the Results of Investigations Made in Experiment Stations in Technical Scientific Journals, Including the Journal of Agricultural Research, R. Pearl (pp. 186-191) previously noted (E. S. R., 33, p. 401); Effective Correlation of Station and Extension Workers, viewed from the standpoint of the extension director, Bradford Knapp (pp. 199, 200); The Effective Correlation of Station and Extension Workers from the Standpoint of Station Work, C. E. Thorne (pp. 200-202); The Best Means of Securing Proper Recognition and Credit for Station Work in Extension Work, H. L. Russell (pp. 202, 203); What Can the Stations do to Encourage More Men to Fit Themselves for Advanced Research? C. D. Woods (p. 206); The Place Which Demonstration Should Have in Extension Work, Bradford Knapp (pp. 209-213); County Organization of Extension Work in Agriculture and Home Economics, C. A. Keffer (pp. 214-219); The Organization of Cooperative Extension Work, Machinery and Method (in the State), B. T. Galloway (pp. 220-224); The Organization of Cooperative Extension Work, Machinery and Method (in the Federal Department of Agriculture), A. C. True (pp. 228-231); Shall Extension Service Include the Social, Recreational and Educational Improvement of Rural and Urban Districts? W. D. Hurd (pp. 232-241); Organization and Methods of Home Economics Extension, Mrs. H. W. Calvin (pp. 241-246); and Home Demonstrations, Miss Mary E. Creswell (pp. 247-252).

The proceedings of the convention of the Land-Grant College Engineering Association include the report of a special committee on fees for professional (engineering) services in land-grant colleges (pp. 259–265); report of the committee on extension texts (pp. 271–274); and the following addresses: Presidential Address, H. W. Tyler (pp. 257, 258); Adaptation of Engineering Education to Local Needs, A. W. Richter (pp. 274-277); Correlation of Courses of Study in Engineering, G. A. Covell (pp. 277–281); Bill for the Establishment of Mechanic Arts Experiment Stations, O. L. Waller (p. 281); The Adaptation of Engineering Experiment Stations to Local Needs, F. E. Turneaure (pp. 281–283); The Relation of the Engineering Experiment Station to the College of Engineering, C. S. Nichols (pp. 284, 285); and Lessons to be Drawn from the Experience of the Agricultural Experiment Stations, O. V. P. Stout (pp. 286–294).

The progress of productive pedagogy, S. G. Rubinow (School and Society, 2 (1915), No. 51, pp. 879-884).—The author gives an account of the progress of agricultural instruction, beginning with the organization of agricultural societies in 1785.

The home project as the center v. the home project as the outgrowth of agricultural instruction, C. G. Selvig (School Ed., 35 (1916), No. 6, pp. 4, 5) .-The author holds that home project work may more profitibly be organized as an outgrowth than as the center of agricultural instruction. Students electing agriculture should have a complete course as organized for their community, embracing definite class, laboratory, and home work. It is a waste of time and effort to treat each individual separately through his separate and distinct project in home work, as the most important general principles, which are of importance to all, can better be taught in the regular classes. Further, while the requirement of some home project will increase the student's grasp of all phases of instruction involved in it, it is impossible to embody all principles in any such project, and it must necessarily be considered somewhat incidental in the course. Hence home project work should not be substituted for class work, but should be organized into a closer relationship with theory and practice. The author considers the productive home project, excepting perhaps a garden or poultry project, of no interest to 80 per cent of the boys in Minnesota high-school classes in agriculture. Out of 104 of these schools reporting, 66 report some form of home project work, and 15 will require such work this year.

Problems in farm woodwork, S. A. BLACKBURN (Peoria, Ill.: The Manual Arts Press, 1915, pp. 129, fig. 60).—This book aims to present the forms, dimen-

sions, and other construction data for objects that can be correlated with work in agriculture in agricultural, high, industrial, and country schools. It includes problems dealing with the shop, poultry raising, seed-corn storage, the yard, house, and garden, stock raising, the barnyard, beekeeping, concrete forms, etc.

Ohio Agricultural Day (Columbus, Ohio: Bd. Agr., 1915, pp. 31, figs. 5).—This manual contains program material and suggestions for the observation of Agricultural Day in Ohio, on November 12, 1915, by the schools, churches, granges, chambers of commerce, and other organizations.

MISCELLANEOUS.

Annual report of the director of the experiment station on work done under the local experiment law in 1915, J. F. Duggak (Alabama Col. Sta. Circ. 34 (1916), pp. 31).—This includes a report by the director on the progress of the work under this law (E. S. R., 24, p. 400), a financial statement for the year, and reports from heads of departments, including detailed reports of boys' and girls' club work.

Abstracts of papers not included in bulletins, finances, meteorology, index (Maine Sta. Bul. 245 (1915), pp. 289-334+XVI, fig. 1).—This contains the organization list of the station; abstracts of 14 papers published elsewhere and previously noted, and an abstract of the paper noted on page 279 of this issue; meteorological observations noted on page 209; a financial statement for the issual year ended June 30, 1915; an index to Bulletins 235 to 245, inclusive, which collectively constitute the thirty-first annual report of the station; an index to the reports from 1911 to 1915; and announcements as to the work, personnel, publications, and equipment of the station.

Fourth and Fifth Annual Reports of the Dickinson, North Dakota, Substation, 1911 and 1912 (North Dakota Sta. Rpts. Dickinson Substa., 1911, pp. 14; 1912, pp. 17).—These reports contain the organization list and an administrative report on the work of the substation during the years 1911 and 1912, respectively, including meteorological data noted on page 209 of this issue.

Sixth Annual Report of the Dickinson, North Dakota, Substation, 1913 (North Dakota Sta., Rpt. Dickinson Substa., 1913, pp. 40, figs. 11).—This contains the organization list and a report on the work of the substation during 1913. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Report of the Hood River, Oregon, Branch Experiment Station, 1913–14 (*Oregon Sta., Bien. Rpt. Hood River Sta., 1913–14, pp. 50, fig. 1*).—This contains reports of the director of the Oregon Station and heads of departments on the work of this substation, the experimental features of which are for the most part abstracted elsewhere in this issue, and an article on The Farm Vegetable Garden noted on page 234.

Report of the Umatilla, Oregon, Branch Experiment Station, 1914, R. W. Allen (Oregon Sta., Rpt. Umatilla Sta., 1914, pp. 11, figs. 2).—This contains a description of the substation, its resources and purposes, soil, climatic, and other conditions, and types of experimental work, and discusses the value of the substation. See also a previous note (E. S. R., 30, p. 441).

Twenty-eighth Annual Report of Rhode Island Station, 1915 (Bul. R. I. State Col., 11 (1916), No. 4, pp. 23-29, 37-39).—These pages include a report of the director and a financial statement for the fiscal year ended December 31, 1915. The experimental work reported with field crops is abstracted on page 229 of this issue.

Index to Farmers' Bulletins Nos. 1-500, prepared by C. H. Greathouse (U. S. Dept. Agr., Index Farmers' Buls. 1-500, pp. 432).

NOTES.

Connecticut State Station.—G. L. Davis, assistant chemist since 1913, terminated his work at this station in June.

Iowa College.—George W. Iverson, instructor in agricultural engineering, has resigned to become farm-engineering editor of a chain of agricultural publications.

Kansas College and Station.—The honorary degree of LL. D. was bestowed upon President H. J. Waters by the University of Missouri at its recent commencement.

Dr. C. M. Brink, professor of English literature and dean emeritus of the college, died June 29. He had been with the institution since 1902 and served as dean of the college from 1909 until his recent retirement.

W. A. Lippincott, poultry husbandman, has been given a year's leave of absence for graduate work in genetics at the University of Wisconsin.

In the extension division, Miss Minnie Sequist has been appointed specialist in home economics and Miss Mary Wright specialist in domestic arts, both appointments beginning September 1. R. P. Schnacke and F. B. Williams have been appointed county agents for Pawnee and Marshall counties, respectively, and have entered upon their duties. Including the 16 county agents and 5 district agents at work in the State, there are now 42 men and 6 women devoting full time to the extension work of the college. A conference of the members of the division of extension was held at the college June 12–17 for the discussion of organization, policies, and relationship between county and district agents, extension specialists, and specialists of the division of agriculture.

Minnesota University and Station.—Dr. R. A. Gortner, associate professor of soil chemistry, has been transferred to the division of agricultural biochemistry with the title of associate professor of agricultural biochemistry and in charge of the section of biochemical research.

Missouri Station.—Henry Cohn has succeeded C. E. Deardorff, resigned, as assistant in the soil survey. A. F. Ridgway has been appointed assistant in veterinary science.

Nebraska University and Station.—Dr. Raymond J. Pool has been appointed permanent head of the department of botany. C. A. Helm, instructor and assistant in experimental agronomy, has resigned to become assistant professor of agronomy in the University of Missouri. William Rabak has been appointed instructor in agricultural chemistry and assistant in agricultural chemistry in the station.

New Jersey Stations.—Samuel U. Hoddeson and Joseph J. Williams have resigned as assistant chemists. Louis J. Kleinfeld and D. James Kay have been appointed assistant chemists; H. C. Haines, assistant extension specialist in fruit growing; Miss E. P. Leeds, assistant State leader of girl's club work; and David Schmidt, field assistant in horticulture.

EXPERIMENT STATION RECORD.

Vol. 35.

SEPTEMBER, 1916.

No. 4.

As the years go by, the annual acts making appropriations for the support of the Federal Department of Agriculture are coming to be recognized more and more as of wide public interest. They serve to epitomize the development and progress of the Department and to emphasize its intimate relations with the daily life of the whole American people. They constitute the medium in which provision is made from time to time for new and enlarged activities, as in the development of demonstration work and the prosecution of marketing studies. Quite frequently they embody important pieces of legislation, as in the meat-inspection amendment of 1906, the Nelson amendment of 1907 increasing the appropriations to the agricultural colleges, and the virus-serum-toxin and the migratory-bird provisions of the act of 1913.

The latest of these acts, covering the fiscal year ending June 30, 1917, is fully as important and interesting in these respects as any of its predecessors. It considerably extends and enlarges the functions and activities of the Department and establishes a new high-water mark in the appropriations for its maintenance. Among other provisions it materially increases the funds available for marketing studies, the eradication of the cattle tick in the South, the combating of rabies in the Rocky Mountain States, and the farmers' cooperative demonstration work outside the cotton belt, as well as for most of the regulatory services of the Department. It inaugurates a market news service and includes, as a new item, studies and demonstrations of methods for obtaining potash on a commercial scale. It provides for the expenditure of \$3,000,000 for additional purchases of lands in the White Mountains and the southern Appalachian system for development as National Forests. It repeals the United States Cotton-Futures Act of 1914 and substitutes a modification of that measure, and it embodies, among other new legislation, provisions to be known as the United States Grain-Standards Act and the United States Warehouse Act.

The new law was introduced into the House of Representatives March 4, following hearings extending over a period of nearly six weeks. As usual, many of its provisions received detailed considera-

tion from Congress, and it did not finally become law until August 11. During the interval which followed the termination of the preceding fiscal year on June 30 the maintenance of the Department was provided for by the passage of special acts extending the appropriations, under certain restrictions, on the basis of the act for the previous year.

The appropriations carried in the new act aggregate \$26,948,852. This is an increase of \$2,349,763 over the estimates submitted by the Department and an increase of \$3,977,070 over the amount carried in the act for the previous year. If comparison between the two fiscal years 1916 and 1917 is attempted, however, an addition should be made to the appropriations for the former year of deficiency items aggregating \$395,000, and a deduction of \$2,000,000 made from those carried by the new act, since this sum, provided for forest reserve purchases, is not available until the following year. On this basis the increase becomes \$1,582,070.

Considering the allotments to the various Bureaus, the Weather Bureau receives \$1,747,260. This is an increase of \$81,210, of which \$40,000 is for the extension of the weather service to the Carribean Sea region, the Panama Canal Zone, and Alaska. It also includes \$10,000 for an extension of the frost-warning and river and flood control work and \$22,500 for the erection of a building at Cape Henry, Virginia.

The appropriations directly allotted to the Bureau of Animal Industry aggregate \$3,020,746, but this is supplemented by extensive funds provided elsewhere. The total corresponding allotments for the previous year were \$2,585,336, so that the increase granted is considerable.

The inspection and quarantine work of the Bureau against animal diseases receives \$532,780, a decrease of \$75,000, due to the reduced area under quarantine for sheep and cattle scabies. For pathological studies of animal diseases \$138,020 is granted, of which \$50,000 is a new item authorizing work on contagious abortion.

For the tick-eradication campaign an appropriation of \$632,400 is given, and it is expected that this will be supplemented by State and county funds sufficient to make a total of nearly \$1,000,000. Of this amount \$50,000 may again be used for live-stock and dairy demonstration work in cooperation with the States Relations Service in areas freed of ticks. During the past year 49,629 square miles of territory were freed from infestation, reducing the area under quarantine to 453,761 square miles. It is now believed that complete eradication is entirely feasible.

The act carries \$360,000 to continue the hog-cholera work, of which \$175,000 may be used for the enforcement of the virus-serum-toxin

act and \$35,000 for research. An allotment of \$75,000 is also made for the investigation, treatment, and eradication of dourine.

The eradication of foot-and-mouth disease is followed by a reduction in the emergency appropriation for this and similar diseases from \$2,500,000 to \$1,250,000, plus the unexpended balance of \$655,790.93 from the previous year. This amount is available not only for the actual combating of the diseases but for the payment of claims in connection with outbreaks. It is provided that payments may be made for animals hereafter purchased on an appraisement based on their meat, dairy, or breeding value, but in case of appraisement on the basis of breeding value it can not exceed three times the meat or dairy value of the animals, and except in extraordinary emergency Federal payments can not exceed one-half the appraisement.

The meat-inspection work is continued much as at present, a permanent appropriation of \$3,000,000 per annum being augmented by a supplementary allotment of \$344,500.

A net increase of \$27,620 is provided for the encouragement of dairying and one of \$19,260 for that of animal husbandry, making \$277,470 and \$208,320, respectively, available for these purposes. It is planned to extend especially the studies in dairy farming, dairy research, the milk and cheese investigations and demonstrations, and the studies of pork production, Shorthorn cattle breeding, poultry breeding, range sheep breeding and management, and the classification of wools.

A special appropriation of \$60,000 is continued for the work in live-stock production in the cane-sugar and cotton districts, now being conducted in close cooperation with the State of Louisiana. This State has deeded to the Department a farm of about 500 acres at New Iberia, and this farm has been divided into four tracts for work with horses and mules, beef cattle, dairy cattle and hogs, and hogs alone. A large number of demonstrations and other extension work in animal production and dairying are also under way. Somewhat similar work is contemplated under a new appropriation of \$40,000 for experiments in dairying and live-stock production in semiarid and irrigated districts of the Western States.

The Bureau of Plant Industry receives an increase from \$2,139,150 to \$2,537,120, its appropriations being divided as usual among a large number of projects. Among the most important new items is that allotting \$250,000 and the unexpended balance of about \$85,000 from a deficiency appropriation of \$300,000 from the previous year for continuing the campaign against the highly infectious disease known as citrus canker. Another large increase is that of \$30,000 for studies of white-pine blister rust and other epidemic tree diseases.

Other extensions of work provided for include \$6,500 for studies of tobacco diseases, \$5,000 for citrus and subtropical fruit diseases and a like amount for breeding disease-resistant citrus varieties, \$2,500 for carrying on soil studies in connection with the powdery scab of potato, \$5,000 for extension work in cotton growing and \$3,000 for cotton diseases, \$5,000 for the development of work on plant-infesting nematodes, \$8,350 for establishing a new grainstandardization laboratory in Minnesota, \$7,500 for studies on the handling, grading, and transportation of the grain sorghums, \$7,500 for studies of the water requirements of crops in the irrigated regions, \$22,500 for investigations of black rust and stripe rust of wheat, oats, and barley, and other cereal diseases, \$10,000 for the development of an American sugar-beet seed industry, and \$21,000 to extend and develop the forage-crop investigations and provide for the more effective distribution of new and rare varieties of seeds. The seed-importation act of 1912 is extended to include vetch and rve grass, and the importation of seed of Kentucky bluegrass and Canada bluegrass is prohibited unless containing at least 50 per cent of live pure seed, while the importation of all other seed subject to the act is prohibited unless it contains 65 per cent of live pure seed. The congressional seed distribution is continued on the usual basis with an allotment of \$252,540.

The allotments for the Forest Service, as usual, far exceed those for any other bureau. The aggregate is \$8,549,735, but, as previously explained, \$3,000,000 of this sum is for additional purchases under the Appalachian Forest Reserve Act, \$2,000,000 of which is not available until July 1, 1917. An appropriation of \$100,000 is also continued for cooperation with the States in fire protection work under the same act. Authority is granted for the prospecting, development, and utilization of the mineral resources of these lands and for the President to set aside suitable areas thereon for the protection of game animals, birds, and fish. In each case regulations are to be prescribed by the Secretary of Agriculture. An arrangement is made whereby timber purchasers may henceforth advance the cost of brush disposal on their cuttings on National Forests, in which case the Department itself will carry on this work at safe and opportune times. The remaining work of the Service is provided for without substantial change, provision being made for the continued administration, protection, and development of the National Forests, and for the varied investigations relating to the practice of forestry and the utilization of forest products.

The appropriation for the Bureau of Chemistry aggregates \$1,153,801, of which over half is for the enforcement of the Food and Drugs Act. The purchase and equipment of a traveling laboratory at a cost of \$7,500 is authorized. The various lines of work

under way are continued without change, and \$50,000 is added for studies of the utilization for coloring purposes of raw domestic materials. The Bureau has been studying dyestuffs, more particularly with reference to their use in food products, for over ten years, and it is planned to continue this work, extending it to methods of manufacture of dyes from domestic products. The studies of naval stores were also definitely assigned to the Bureau of Chemistry, and \$5,000 additional was granted to carry on demonstrations of improved methods for preparing these commodities.

The Bureau of Soils is granted \$175,000 for experiments and demonstrations to determine the best methods of obtaining potash on a commercial scale. The remaining lines of work of the Bureau are continued unchanged, the total appropriation being \$503.735.

An increase of \$38,980 is accorded the Bureau of Entomology. This is divided among a number of projects, including extension work in bee culture, and studies of the grape-berry moth, clover seed midge, clover root borer, tobacco hornworm, insects instrumental in the carriage of cucumber diseases, and biting flies and other insects affecting the health of domestic animals. The gipsy and brown-tail moth campaign is allotted \$305,050 and the Bureau as a whole \$868,880.

The Bureau of Biological Survey is granted \$578,230. The principal change is an increase of \$125,000 to be used on the public lands, National Forests, and elsewhere in the Western and Northwestern States to combat the spread of rabies by destroying wolves, coyotes, and other predatory wild animals. This appropriation followed a serious outbreak of the disease in these States. in which serious losses to live stock and even human cases of the disease resulted from an epidemic among coyotes, and continues work begun earlier in the year under a deficiency appropriation of \$75,000.

The total appropriation for the States Relations Service is \$2,969,680, as compared with \$2,821,840 for the previous year. The main item of increase is one of \$100,000 for the farmers' cooperative demonstration work outside the cotton belt. This will permit of considerable further extension of that work and of initiating in a small way extension work by women county agents. There is also an increase of \$23,000 for the experiment stations in Alaska, Hawaii, and Porto Rico. Most of this increase is in lieu of the receipts from the sales of farm products which were formerly available to the insular stations for carrying on their work, but which, since June 30, 1915, have been required to be deposited in the United States Treasury to the credit of miscellaneous receipts and are not available for station use. Additional funds are likewise provided for the administrative and general expenses of the Service by reason of its

increased activities. The other lines of work, including the maintenance of the State experiment stations, the farmers' cooperative demonstration work in the cotton belt, the study of farmers' institutes and agricultural schools, and the investigations in home economics are continued on the existing basis.

The funds allotted to the Office of Markets and Rural Organization are nearly doubled, the total of \$872,590 allowing for a considerable expansion in its work. During the crop season of 1915 an experimental news service was conducted, giving timely information on the movements and prices of the strawberry, tomato, cantaloup, and peach crops, with such successful results that \$136,600 is now provided for systematic service in the collection and distribution of market news by telegraph for perishable fruits and vegetables and by mail for other farm products. Other new items are \$65,000 for the gathering of information pertaining to the marketing of live stock and its products and \$35,000 for cooperation with the States in marketing studies. An increase from \$238,000 to \$285,000 is granted for other marketing and distribution studies, notably for additional attention to cooperative purchasing and marketing, market grades and standards, marketing business practice, and the marketing of live stock, meats, animal by-products, dairy products, grain, seeds, and hay. The Office also receives \$48,000 to continue the cotton-standardization work and \$32,860 for its studies in rural organization.

An increase from \$50,000 to \$75,000 is provided for the enforcement of the plant-quarantine act by the Federal Horticultural Board. Of this sum \$15,000 is to be used to prevent the introduction of the pink bollworm, one of the most serious cotton pests known, and \$10,000 for the inspection of imported potatoes to guard against potato wart and other diseases and insect pests.

The work of the remaining branches of the Department is continued on substantially the present basis, both as to funds and lines of work. The Bureau of Crop Estimates receives \$316,436, an increase of \$32,956, mainly for the employment of additional field agents and specialists, notably in truck and fruit crops. The Office of Public Roads and Rural Engineering is granted \$599,200, an increase of \$12,735; the Office of the Secretary \$688,160, of which \$285,810 is for the Office of Farm Management; the Division of Accounts and Disbursements, \$44,920; the Division of Publications, \$197,650; and the Library, \$49,520. The Department is again allotted \$105,000 for the enforcement of the insecticide act, \$40,000 to continue demonstration work on reclamation projects, and \$123,689 for rent of buildings in the District of Columbia, and receives \$122,500 for miscellaneous expenses.

Exhibits by the Department are provided for at the International Soil Products Exposition to be held at El Paso, Texas, October 17–26, and at the National Dairy Show at Springfield, Massachusetts, October 12–21, with appropriations of \$20,000 and \$15,000, respectively. The former exhibit is to be illustrative of farming methods in the subhumid, arid, and semiarid regions of the country, and the latter of the boys' and girls' club work and other features of the extension work carried on in the North Atlantic States. The President is authorized to extend invitations to other nations to participate in the International Farm Congress and the International Irrigation Congress, both of which are to be held at El Paso.

Reference has already been made to the trio of noteworthy measures appended to the main portion of the act and designated respectively as the United States Cotton-Futures Act, the United States Grain-Standards Act, and the United States Warehouse Act. These measures are all designed to alleviate some of the difficulties which have frequently confronted farmers in the marketing of the staple agricultural crops.

The United States Cotton Futures Act, as reenacted, follows substantially the text of the act passed in 1914. That measure, it will be recalled, was a taxing statute designed to regulate future trading in cotton so that it would be fairly conducted and truly reflect the values of spot cotton. It imposed a tax at the rate of two cents per pound on all contracts of sale of cotton for future delivery entered into on exchanges and like institutions, unless such contracts complied with certain conditions which were calculated to eliminate certain recognized evils in future dealings. Among the conditions necessary to be met in order to exempt a contract from the tax were the use of the official cotton standards of the United States established under the act, and of actual commercial differences in the settlement of such contracts as ascertained from actual sales of cotton in bona fide spot markets. The act also taxed orders sent from the United States for the making of future contracts on exchanges in foreign countries, unless the contracts made on the foreign exchanges complied with certain conditions. The Secretary of Agriculture was given authority to establish the official standards, to designate the bona fide spot markets, and to determine disputes referred to him by the parties to future contracts involving the grade, length of staple, or quality of cotton offered for delivery thereunder. The most important changes made in the new act are the omission of the tax on orders sent abroad for the making of future contracts and the addition of authority for the Secretary of Agriculture in settling disputes to include in his findings a complete classification of the cotton involved. The new act became effective September 1, an appropriation of \$120,750 and the unexpended balances from appropriations for the previous measure being available for its enforcement.

The United States Grain-Standards Act authorizes the Secretary of Agriculture to investigate the handling and grading of grain, establish official standards, license grain inspectors, and otherwise administer its provisions. After the standards for a grain have become effective, all shipments by grade in interstate or foreign commerce must either be inspected by a licensed inspector at the point of shipment, during transit, or at the point of delivery, or, if there are no inspection facilities available, may be marketed uninspected but subject to the right of either party to the transaction to refer any dispute as to the grade to the Secretary of Agriculture for his determination. An appeal to the Secretary may also be taken as to the true grade of grain which has been inspected. The findings of the Secretary in cases of dispute and appeals are made prima facie evidence in court proceedings.

The certifying of an official grade on shipments subject to Federal supervision is restricted to inspectors holding Federal licenses. These licenses are to be issued to persons authorized to inspect and grade grain under State laws, or may be issued to any competent and disinterested person, and may be suspended or revoked for cause. A complete system of records and reports is required of inspectors, and penalties are provided for false grading, interference with officials, and other violations of the act.

The legislation is designed to facilitate the use of more uniform grades in handling grain, thus simplifying the relations between the producer, dealer, and consumer. Since the final decision as to the grade of a shipment rests with the Department, it is also expected that the grower may more readily obtain higher returns for a product of superior merit, thus supplying him with a financial incentive to improve its quality. An appropriation of \$250,000, available until expended, is made for the enforcement of the act.

The central purpose of the United States Warehouse Act is to establish a form of warehouse receipt for cotton, grain, wool, tobacco, and flaxseed which will make these receipts easily and widely negotiable as delivery orders or as collateral for loans, and therefore of definite assistance in financing crops. This purpose the act aims to attain by authorizing the licensing of bonded warehouses under conditions which will insure the integrity of their receipts and make these receipts reliable evidence as to the condition, quality, quantity, and ownership of the products for which they are issued.

The Secretary of Agriculture is given authority to inspect, classify, and license warehouses when found suitable for the storage of these commodities, as well as to establish official standards for them, to

issue licenses to competent persons to classify and weigh the products to be stored in the warehouses, and to conduct warehouse investigations. The system of licensing is entirely voluntary, but provides for Federal licenses, when desired, for warehouses in which cotton, grain, wool, tobacco, and flax may be stored for interstate or foreign commerce, or located in places under the exclusive jurisdiction of the United States, or owned, operated, or leased by any State. Applicants must agree to comply with the act and the rules and regulations prescribed under it and give bond to secure the performance of their obligations. The form of receipt and manner of delivery of products are prescribed in detail, and records and reports are subject to examination by the Department. All grain, flaxseed, or other fungible products stored in these warehouses for interstate or foreign commerce must also be inspected and graded by persons licensed for the purpose. The licenses may be revoked for cause, and penalties are provided for fraudulent transactions. The Warehouse Act became effective at once and carries an appropriation of \$50,000, available until expended, for its enforcement.

In a discussion of the appropriation act as a medium for the support of the Department of Agriculture, reference should also be made to the funds administered by it but appropriated in other ways. For the fiscal year under discussion, what are termed the permanent appropriations under the Department will aggregate \$10,604,000, the largest items being those of \$5,000,000 for the construction of rural post roads under the law recently described (E. S. R., 35, p. 200), of which not to exceed \$150,000 may be used by the Department for administering the act; \$3,000,000 for meat inspection; and \$1,580,000 under the Smith-Lever Extension Act; the remainder being chiefly for payments to the States as their quota of the receipts from the National Forests. There is also the appropriation for the Department printing and binding, carried as usual in the appropriation act for sundry civil expenses. This appropriation has been increased from \$500,000 to \$600,000, of which \$47,000 is for the Weather Bureau and \$177,500, an increase of \$40,000, for use in the publication of Farmers' Bulletins.

Nor are the Federal appropriations for agricultural purposes confined to the Department of Agriculture. The usual large appropriations will be available for agricultural education in the land-grant colleges under the Morrill and Nelson Acts, as well as the smaller grants for the rural education work of the Bureau of Education, demonstration work among the Indians, and the payment of the country's quota toward the support of the International Institute of Agriculture. The aid granted under the Federal Farm Loan Act

has been already discussed (E. S. R., 35, p. 101). A provision is also carried in the National Defense Act of June 3, 1916, for an investigation of means for the production of nitrates and other products for munitions of war and useful in the manufacture of fertilizers, and for the construction and operation by the Government of a plant or plants to manufacture these products. This enterprise carries an appropriation of \$20,000,000.

The substantial aid tendered to agriculture in these various ways indicates anew the increasing popular realization of the responsibility of the Federal Government in the development of the Nation's basic industry. The program of work outlined for the coming months is unusually broad and comprehensive, and extends the functions of the Department in a number of new and important directions. It augments especially its administrative and regulatory powers, but it also provides more liberally than ever before for the development of scientific research and the dissemination of agricultural knowledge. There will be general concurrence in the view expressed by President Wilson, after signing the appropriation act, that it will tend to "result in making agriculture more profitable and country life more comfortable and attractive, and therefore insure the retention in rural districts of an efficient and contented rural population."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Practical physiological chemistry, P. B. Hawk (Philadelphia: P. Blakiston's Son & Co., 1916, 5. ed., rev. and enl., pp. XIV+638, pls. 6, figs. 172).—This is the fifth edition of the volume previously noted (E. S. R., 21, p. 63). The chapters on nucleic acids and nucleoproteins, gastric analysis, intestinal digestion, blood analysis, and metabolism are new and have been inserted to increase the usefulness of the volume and to keep thoroughly abreast with recent developments in physiological chemistry. The latest methods of quantitative analysis have also been introduced throughout the volume. Thirty-five new illustrations have been incorporated.

Yearly report in regard to the progress made in agricultural chemistry, edited by T. Dietrich and F. Mach (Jahresber. Agr. Chem., 3. ser., 17 (1914), pp. XXIX+563).—A report of the work of 1914 in continuation of that previously noted (E. S. R., 34, p. 311).

Report of the committee on editing methods of analysis (Jour. Assoc. Off. Agr. Chem., 1 (1916), No. 4, pt. 2, pp. 57, figs. 4).—This report contains the recommendations of the committee on editing methods for official and tentative methods of analysis of fertilizers, soils, inorganic plant constituents, waters, and tanning materials, presented at the annual meeting of the Association of Official Agricultural Chemists, November 16–17, 1915.

On the origin of the humin formed by the acid hydrolysis of proteins, R. A. Gortner and M. J. Blish (Jour. Amer. Chem. Soc., 37 (1915), No. 6, pp. 1630-1636; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8, p. 1026).—It has been demonstrated that "in all probability the humin nitrogen of protein hydrolysis has its origin in the tryptophan nucleus." When tryptophan is boiled alone with mineral acids no humin is formed; when protein or carbohydrate is present, however, an abundance is formed. With large amounts of carbohydrate present nearly 90 per cent of the tryptophan nitrogen remains in the humin fraction. Histidin causes no increase of nitrogen in the humin fraction and can be quantitatively recovered in the bases. The humin is probably formed by condensation of an aldehyde (formed by the action of the acid on carbohydrate) with the NH group of the tryptophan nucleus. It is indicated that a distinct value can thus be assigned to the humin nitrogen determinations.

Fractionation of the phosphotungstic-acid precipitate with acetone as a useful method for the preparation of the vitamin fraction from yeast, C. Funk (Biochem. Bul., 5 (1916), No. 17, pp. 1-16).—The author has demonstrated that "the phosphotungstate precipitate from alcohol extract of yeast can be divided, by means of acetone, into two fractions: A small insoluble fraction which contains the bulk of vitamin, and a large soluble one which is totally inactive." Lead acetate was used to decompose the phosphotungstates instead of baryta, as this procedure offered the advantage of yielding clear solutions which facilitated further purification and avoided the use of alkali. From autolyzed yeast an insoluble fraction could be obtained by the acetone method which represented 34 per cent of the total phosphotungstate precipitate.

The molecular weights of certain vegetable oils, H. J. BACKER (Chem. Weekbl., 12 (1915), No. 47, pp. 1034-1040; abs. in Analyst, 41 (1916), No. 479, p. 47).—The average molecular weights of a number of vegetable oils, calculated from the lowering of the freezing point, are submitted, as follows: Coconut oil 613, cohune nut oil 625, arachis oil 803, cato seed oil 803, cato seed oil (hydrogenated) 884, linseed oil 796, maize oil 796, mustard seed oil 928, olive oil 803, palm kernel oil 644, rape oil 892, castor oils 844 and 1,031, sesame oil 800, and soy-bean oil 783. A commercial sample of blown rape oil showed a molecular weight of 1,335.

Other physical constants of these oils are also given.

Philippine oil-bearing seeds and their properties, H. C. Brill and F. Aggaoili (Philippine Jour. Sci., Sect. A, 10 (1915), No. 2, pp. 105-121, figs. 2; abs. in Ztschr. Angew. Chem., 29 (1916), No. 18, Referatenteil, p. 114).—The percentage yields, chemical constants, physiological properties, and commercial possibilities of several Philippine oils have been studied and the results reported in detail.

It has been demonstrated that the oil from the lumbang bato (Aleurites moluccana) and lumbang banucalag (A. trisperma) are drying oils of high quality, comparing favorably with linseed and Chinese wood oils, while the oil from the nuts of the calumpang, cato (Chisochiton cumingianus) kapok, pili, palo maria de la playa (Calophyllum inophyllum), and palo maria del monte (C. wallichianum) have no appreciable drying qualities.

On the heating of hay during the curing process, F. W. J. BOEKHOUT and J. J. O. DE VRIES (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 19 (1916), pp. 61-80, fig. 1).—Analytical data of a number of samples of gas obtained in the curing of hay are submitted in detail.

The heating in the process of curing is largely attributed to a purely chemical action in which iron acts as a catalyzer. Bacteria and enzyms also play an important rôle in the process. Attempts to sterilize the hay with a 2 per cent solution of copper sulphate were unsuccessful, since the growth of yeasts and molds could not be controlled by this treatment. The production of furfurol in the curing of hay, as noted by earlier investigators, was confirmed.

[The nature of the coloring matter of sugar cane], M. A. Schneller (Louisiana Stas. Rpt. 1915, pp. 13, 14).—Preliminary results indicate that "substances belonging to the polyphenols are present in cane, especially the eyes and tops, and cause in connection with iron the dark color of juice and sirup, The action of boiling temperatures and sulphur dioxid in the sugar houses results only in a temporary decomposition and reduction of the polyphenol iron compound and decolorization of the products. The darkening of plantation white sugars in storage must be sought in reoxidation of adhering or occluded traces of the iron polyphenol. Decomposition products of a similar nature (glucinic acid) are also formed by the action of lime at alkaline reaction on glucose. Alkalinity is, however, avoided in the white sugar manufacturing in this State. A means of elimination of the polyphenols could be found in the boneblack process, generally discarded as too costly. Elimination of iron by secondary carbonation, or a similar process, has the same result, but would be successful only if further contact of the liquors with iron were completely avoided. Lining of the iron equipment with rust-proof enamel might lead to a distinct

"The incrusting coloring matter of cane fiber, although perhaps the physiological product of the above-mentioned polyphenols and of a similar chemical composition (coniferin or a derivative), does not yield dark-colored iron com-

pounds and owing to its firm combination with the lignin of the cell walls is only separated with difficulty and would not easily pass into the juice."

Studies on the relation of cement dust to citrus vegetation.—I, The effect on photosynthesis, H. D. Young (Biochem. Bul., 5 (1916), No. 18-19, pp. 95-100).—The investigation has shown that the coating of dust on orange leaves adjacent to cement plants amounted in many cases to as much as 0.0034 gm. per square centimeter and corresponded in composition very closely to the "raw mixture" from which the cement was made. The amount of dust found on such leaves may shut out as much as 80 per cent of light from the upper surface of the leaf. This exclusion of light, however, does not interfere with the carbohydrate synthesis. The metabolic activity of new leaves was only slightly greater than that of old leaves.

Researches on arginase; concerning the action of arginase on creatin, A. CLEMENTI (Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. c Nat., 5. ser., 24 (1915), I, No. 5, pp. 483-489).—It has been demonstrated that creatin is not hydrolyzed into urea and sarcosin by arginase, thus confirming the previous finding of Dakin.^a Arginase is not a ferment capable of detaching the guanidin nucleus from any compound to which it may be bound, as would be indicated by the name "deguanidase," which has recently been proposed. The inability of arginase to hydrolyze creatin supports the contention of the specificity of the enzym.

Adsorption of invertase, J. M. Nelson and E. C. Griffin (Jour. Amer. Chem. Soc., 38 (1916), No. 5, pp. 1109–1115).—From the investigation it is concluded "that invertase is colloidal in nature, and the reaction between the enzym and cane-sugar solution depends on the contact of two phases. The activity of invertase . . . is not affected whether or not the enzym is adsorbed to a solid like charcoal, or to a colloid like saponin, serum, or egg albumin, distributed uniformly throughout the solution of the substrate. Displacing the adsorbed invertase by a second colloid is without effect on the activity, contrary to the views held by many. Invertase can be removed from an aqueous solution by adsorption to a solid, and again brought into solution by a second colloid suspended uniformly throughout the solution. Eriksson's proof that cane sugar can liberate invertase adsorbed to charcoal is not valid."

The experimental methods used were those described in the communication previously noted (E. S. R., 34, p. 803).

The occurrence of urease in higher plants, M. W. Beijerinck (Chem. Weekbl., 13 (1916), No. 16, pp. 443, 444).—The author has found urease in the cortex of the twigs and in the buds of Glycine sinensis and Cytisus laburnum. The seeds of the latter were especially rich in urease, although considerably less was found than is present in the soy bean. Its presence was also demonstrated in the bark of the ordinary acacia, Robinia pseudacacia, in the seeds of the indigo plant, and in the tissues of the various herbaceous Papilionaceæ. Its presence could not be determined in peas, beans, flaxseed, almonds, and various other plants examined.

A simple device for regulating the pump used in exhausting a vacuum oven, G. P. Plaisance and D. V. Moses (Jour. Amer. Chem. Soc., 38 (1916). No. 5, pp. 1063-1065, fig. 1).—The authors describe in detail a simple automatic device for maintaining any desired pressure in a Freas electrically heated vacuum oven. The apparatus is easily assembled and has given entire satisfaction.

A new form of gas burette, Hammermann (Chem. Ztg., 40 (1916), No. 10-11, p. 84, fig. 1).—An apparatus to measure gases only slightly soluble in water, in

which the burette and leveling bulb are mounted together on a Woulff bottle, and its manipulation are described in detail.

A simple, efficient, and economic filter, S. L. Joddel and E. H. Kelloge (Biochem. Bul., 5 (1916), No. 18-19, pp. 87-94).—The authors describe in detail the preparation and use of the paper pulp filter and demonstrate its efficiency by submitting analytical data. Its application to the filtration of the ammonium-phosphomolybdate precipitate in phosphorus determinations is especially indicated.

See also previous notes (E. S. R., 34, p. 712; 35, p. 204).

A modification of the Lunge nitrometer, W. Senften (Chem. Ztg., 40 (1916), No. 4-5, pp. 39, 40, figs. 2).—A modified apparatus, which shortens the time for making determinations by insuring the complete solution of the sample, and its manipulation are described in detail. A new gas burette for use in connection with the apparatus is also described.

The quantitative determination of silica, V. Lenher and E. Truog (Jour. Amer. Chem. Soc., 38 (1916), No. 5, pp. 1050-1063).—After preliminary experiments on the various factors which influence the solubility of silica the following procedure was adopted:

A 0.5 to 1 gm. sample is intimately mixed with 5 gm. of sodium carbonate and fused in a platinum crucible. The cold fusion is treated with 60 cc. of hydrochloric acid (specific gravity 1.07). After all carbonates are decomposed the solution is evaporated on the water bath until the residue begins to crumble. The residue is treated with 15 cc. of hydrochloric acid (specific gravity 1.1), covered, and heated on the water bath for ten minutes. After diluting with 10 cc. of water it is filtered and the silica washed with a hot solution consisting of 5 cc. of hydrochloric acid (specific gravity 1.2) to 95 cc. of water. The filtrate is evaporated to dryness, the residue dehydrated at 110° C. for two hours, taken up with 8 cc. of hydrochloric acid (specific gravity 1.1), covered and heated on the water bath from five to ten minutes, diluted to 50 cc., and filtered immediately, washing with cold water containing 1 cc. concentrated hydrochloric acid to 99 cc. of water. The two portions of silica thus obtained are carefully ignited to constant weight in a platinum crucible and the silica determined by volatilization with hydrofluoric acid after the addition of a few drops of sulphuric acid.

It is indicated that in the sodium-carbonate fusion methods for silicates there is always a nonvolatile residue which contains the various bases and which should be fused again with sodium carbonate and added to the filtrate from the silica when the bases are to be determined.

Dehydrated silica is appreciably soluble in hydrochloric acid of all strengths. This error is, however, negligible when dilute acid is used. The dehydration temperature should be kept below 110°. Excessive amounts of sodium carbonate should be avoided in the fusion, since the subsequently formed sodium chlorid exerts a solvent action on the silica.

Comparative tests of certain methods for the determination of copper in copper sulphate, von Wissell and F. Küspert (Landw. Vers. Stat., 86 (1915), No. 3-4, pp. 277-286).—As a result of the comparison of the various methods used for the determination of copper in fungicidal materials in the presence of iron the thiocyanate procedure was found to yield reliable results and to be the simplest and most economical of all the methods tried, especially where only occasional determinations are necessary.

The Grete volumetric method for the determination of phosphorus in fertilizers, G. INCZE (Kisérlet. Közlem., 18 (1915), No. 5-6, pp. 797-809).—From a critical examination of the method the author has found that the proper prep-

aration of the reagent used in this method is very important, particularly the preparation of the glue solution. The presence of hydrochloric acid, large amounts of iron, and, especially, organic substances influence the correctness of the titration. The water-soluble phosphoric acid in superphosphates and that obtained from Thomas slag by digestion with sulphuric acid can be determined directly after neutralizing the solution. The procedure is applicable to routine analyses, but is not recommended on account of the care and patience required in its manipulation. The accuracy of the method is indicated by submitted experimental data.

The volumetric determination of potassium and its application in the analysis of fertilizers, G. Ajon (Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale, 3 (1915), pp. 91-104).—The procedure described by the author is as follows:

About 25 cc. of a 2 per cent solution of potassium chlorid or potassium sulphate, or an amount equivalent to from 1.08 to 1.26 per cent of potassium oxid, is transferred to a 150–200 cc. Erlenmeyer flask, 50 cc. twice-normal tartaric acid added, and the mixture thoroughly shaken. Twenty-five cc. of half-normal sodium hydroxid is then added and the mixture again strongly agitated for five minutes. To this 25 cc. of 96 per cent alcohol are added and the flask and contents allowed to stand for from six to eight hours. The precipitate thus formed is washed by decantation several times and finally transferred to the filter, where it is thoroughly washed with neutral 96 per cent alcohol. It is then treated with tenth-normal alcoholic sodium hydroxid until strongly alkaline to phenolphthalein, and allowed to set for about five minutes with occasional shaking. When the precipitate is completely dissolved the amount of tenth-normal hydroxid used is determined by titration with standard hydrochloric acid.

The number of cubic centimeters of tenth-normal sodium hydroxid used to dissolve the bitartrate, multiplied by 0.00471, gives the amount of K₂O present in the original solution. Analytical data submitted indicate the accuracy of the method.

The use of enzyms and special yeasts in carbohydrate analysis, W. A. Davis (*Internat. Sugar Jour.*, 18 (1916), No. 208, pp. 166-171).—This material has been previously noted from another source (E. S. R., 35, p. 206).

The possibility of titrating the monosubstituted amino group of amino acids with formol, A. Clementi (Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 4, pp. 352-359; Arch. Farmacol. Sper. e Sci. Aff., 21 (1916), No. 6, pp. 215-224; abs. in Chem. Abs., 9 (1915), No. 17, p. 2394).—
The Sörensen formol titration method for the determination of the quantity of amino groups in amino acids has not as yet been applied to amino acids in which the amino group is partly or completely substituted. The author has performed experiments of this kind with sarcosin, and shows that the amino group, even if monosubstituted, reacts with formaldehyde. In titrating monosubstituted amino acids according to Sörensen's method it is, however, necessary to titrate to the intense coloration of phenolphthalein, as otherwise the results will be slightly too low.

Concerning the protein content of meat, N. W. Janney (Proc. Soc. Expt. Biol. and Med., 13 (1916), No. 5, pp. 83, 84).—The author indicates the error inherent in the protein determinations in meat because of the large amount of nonprotein nitrogen present. The average nitrogen content of meat proteins lies between 16.2 and 16.7 per cent, and is not 16 as the factor 6.25 commonly used indicates. The principle involved in a modified procedure for the direct determination of the proteins in muscle is the coagulation of the muscle in alcohol and the removal of nonprotein material by extraction. With proper precau-

tions it is possible to separate completely the fatty and other nonprotein material from the proteins so that they can be obtained in a high state of purity.

Analytical data of the protein content of dog, rabbit, chicken, and fish (halibut) muscle are included.

The rapid analysis of milk, G. Pégurier (Ann. Chim. Analyt., 21 (1916), No. 4, pp. 70-73, fig. 1).—The author describes rapid procedures for the determination of the specific gravity, fat, and lactose, to be used in the field for ascertaining the purity and food value of milk. The specific gravity is determined in the usual manner; the fat in an ordinary or a specially graduated test tube, by extraction with an alcohol-ether mixture after the addition of a few drops of alkali; and the lactose by Fehling's solution, after precipitation of the protein with a reagent composed of phenol and acetic and citric acids in 95 per cent alcohol.

Note on human milk, G. D. Elsbon (Analyst, 41 (1916), No. 480, p. 74).—The following figures, obtained from 67 complete analyses representing the average percentage composition of human milk, are submitted: Total solids 11.7, protein 1.19, fat 3.11, ash 0.21, solids-not-fat 8.59, and lactose 7.18 per cent. In 79 other samples the total solids averaged 11.78, fat 3.28, and solids-not-fat 8.5 per cent.

[Methods of direct sucrose determinations in the presence of reducing sugars], M. A. Schneller (Louisiana Stas. Rpt. 1915, p. 14).—In the methods based on the action of small amounts of alkali on the rotary power of the reducing sugars several sources of error were found to be inherent, which are summarized as follows: "(1) The residuary levorotation introduces a considerable error, especially with material high in reducing sugar and with methods using a weak concentration of alkali. (2) Stronger concentrations of alkali reduce this levorotation but introduce a second serious error due to the decrease of sucrose rotation by the neutralized alkali. (3) The incidental use of oxidants (as hydrogen peroxid) also causes a destruction of sucrose. Apparently correct results are possible by compensation of errors due to (1) and (3)."

Studies on the analysis and analytical products of glucose, T. VAN DER LINDEN (Arch. Suikerindus. Nederland. Indie, 23 (1915), No. 52, pp. 1979–1994; Meded. Proefstat. Java-Suikerindus., 5 (1915), No. 22, pp. 609–624).—In the analysis of invert sugar by barium or calcium hydroxids at 80° C. the author has obtained appreciable amounts of saccharic and gluconic acid, together with a small amount of oxalic acid. Formic acid was also formed, but the presence of lactic acid could not be determined. The acids were isolated in a pure form by precipitation with neutral, basic, or ammoniacal lead acetate. The experimental procedures used in the work are described in detail.

The American Leather Chemists Association, 1916 (Amer. Leather Chem. Assoc. [By-laws, etc.], 1916, pp. 37).—This pamphlet outlines in detail the official methods for the analysis of vegetable materials containing tannin, for sampling tanning materials, and for leather analysis. Provisional methods for the analysis of sulphonated oils, moellons, and hard greases are also included.

[Report of the] bacteriological department, W. L. OWEN (Louisiana Stas. Rpt. 1915, pp. 11-13).—From results obtained in a study of the deterioration of sugars, and the principal factors affecting it, "it appears that neither the moisture alone, nor when used in conjunction with the factor of safety, furnishes a reliable criterion of the keeping quality of a sugar, but that its degree of infection must also be taken into consideration."

In a study of the species of micro-organisms causing deterioration of sugar, 18 cultures of bacteria and 20 cultures of yeast were obtained from sugar. "There appears to be considerable variation in the deteriorative power of the

different species, which is not altogether obliterated by repeated cultivations. Sugars from widely distant countries show no greater variation in this respect than sugar from adjoining plantations. . . It was observed that the microorganisms found in sugars do not predominate either in the mill juice or on the cane leaves. Analyses showed these sugar deteriorative forms to occur only to the extent of 19.5 per cent in the fresh juice. From this point they increase to 46 per cent and 91.5 per cent in the sulphured and defecated juice, respectively. The filter press appears to be the vital point in determining the infection of the finished sugars."

A distinct and hitherto undescribed species of bacteria, commonly occurring in the interior of borer-infested cane, was isolated and named *Bacterium saccharum officinarum*. "Inoculation experiments upon cane showed... that it is not a great factor in the deterioration of the juice of the growing cane, hence its presence there does not apparently aggravate the deterioration following borer infestation."

The products of the farm slaughterhouse, sausage kitchen, and smoke house, A. Haring and W. Hislop (State Col. Wash., Dept. Ext. Bul. 10 (1916), pp. 23, figs. 6).—This pamphlet discusses the slaughtering of beef cattle, veal, sheep, goats, and hogs, and outlines the methods in use for the curing and smoking of meats. Directions for the preparation of various kinds of sausage, lard, soap grease, and tripe, together with a list of tools for the farm slaughterhouse, are included.

Forest chemistry, Puran Singh (Ann. Rpt. Bd. Sci. Advice India, 1914–15, pp. 10–21).—These pages contain brief comments on minor products distilled from the deodar and their value and uses, the optical rotation of steam-distilled deodar oil, the dry distillation of deodar, the best season for collecting myrobalans as a tannin material, an inquiry as to the possibility of reducing the harshness of tan barks, the manufacture of products from Boswellia serrata and their chemical composition, Indian sumac, use of nickel hydroxid in tannin estimation, camphor in dried camphor leaves, the camphor content of the various parts of a camphor tree, and the determination of moisture in fresh camphor.

The conifer leaf oil industry, A. W. Schorger (Metallurg. and Chem. Engin., 14 (1916), No. 9, pp. 515-518, figs. 4).—This article discusses the conifer leaf oil industry and describes the still and its operation. Certain factors which influence the yield of oil are indicated.

A table giving the yield of oil, specific gravity, and principal constituents of a number of the conifer leaf oils is submitted.

METEOROLOGY.

Illusions of the upper air, N. Shaw (Nature [London], 97 (1916), Nos. 2426, pp. 191-194; 2427, pp. 210-214, figs. 3).—This is a brief review of progress in meteorological theory in England since 1866, showing how the development of upper air research has modified commonly accepted views regarding the atmosphere in general, especially the conception of cyclones and anticyclones, the convection theory, and the general structure of the atmosphere. It is stated that the principal result of this study of the upper air "is the division of the atmosphere into two layers: A lower layer about 10 km. thick, the troposphere, the region of convection; and an upper layer, the stratosphere, in which there is no convection. We can use the information to test some of the generally accepted ideas about cyclones and anticyclones by comparing the results of speculation with the new facts. Many of the pictures which we imagined now appear to have been illusions. Those of us, for example, who thought that because the air was warmed from the bottom, the upper part

would be free from sudden changes of temperature such as we get at the surface were rapidly and rudely disappointed. Simplicity is not apparently the characteristic of the upper air."

Night cooling and the importance of the dew and frost points, J. Schubert (Met. Ztschr., 32 (1915), No. 8, pp. 343-350, figs. 3).—The observations of various investigators bearing on the relations of the temperature of the surface of the earth and the overlying air, and of the pressure and humidity of the air, to the formation of dew and frost are critically reviewed and discussed in this article.

The following are among the conclusions reached from the data cited:

With a given pressure, the frost-point is higher than the dew-point. The frost-point Te may be calculated from the dew-point T within 0.1° by the formula Te=0.9T. For more accurate reckoning for temperatures from 0 to -14° the factor 0.89 should be used. The dew-point runs parallel with the air temperature from midnight to 6 a. m. The surface temperature falls more rapidly than that of the overlying air and may be below the dew-point while the overlying air is still above. Dew begins to form with a humidity of 90 per cent, is greater at 95 per cent, and turns to fog at 99 per cent. The formation of dew results in a distinct lowering of pressure. During the last half of the night the fall of temperature is relatively less with formation of dew and frost than with dry air, due to heat set free by condensation.

Frost protection for fruit and vegetables in the United States (Abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No 1, pp. 36-42).—This is a summary of a number of papers on this subject, most of which have been separately noted in the Record.

The weather of 1915, J. A. Murray (*Rpt. Agr. New Brunswick, 1915, pp. 161-169*).—Observations on temperature, precipitation, and sunshine at Fredericton, N. B., and on temperature at various other places in the Province are tabulated and briefly discussed. The season of 1915 was unusual and unfavorable for farming mainly on account of excessive precipitation and diminished sunshine.

The weather of the past agricultural year, F. J. Brode (Jour. Roy. Agr. Soc. England, 76 (1915), pp. 171-180).—The weather conditions throughout the British Isles during 1915 are summarized as usual and comparisons made with the weather of previous years. It is stated that as a result of a succession of adverse weather influences the yield of crops during the year was generally below the average.

Hailstorms and hail prevention during 1915 in the departments of Gironde and Dordogne, France, A. Angot (Compt. Rend. Acad. Agr. France, 2 (1916), No. 20, p. 558).—This is a brief note on a more detailed report by F. Courty in a bulletin of the Meteorological Commission, the principal conclusion of which is that hailstorms are always irregular in occurrence and distribution, and that the electric tower method of prevention apparently exerts no practical influence on their course or intensity.

Annual distribution of cloudiness in France, G. BIGOURDAN (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 17, pp. 620-625, figs. 13; abs. in Rev. Sci. [Paris], 54 (1916), I, No. 9, p. 285).—This is a report of a complete study for France similar to that which has been undertaken by Teisserenc de Bort for the whole world. Curves, isonèph, connecting points of equal mean monthly cloudiness are given and discussed. Attention is called to the need for this purpose of longer series of observations at a greater number of places.

International catalogue of scientific literature. F—Meteorology (Internat. Cat. Sci. Lit., 12 (1915), pp. VIII+194).—"The literature indexed is mainly that of 1912, but includes those portions of the literature of 1901-1911 in regard

to which the index slips were received by the Central Bureau too late for inclusion in the previous volumes. There are also entries dated 1913." The section on the relation of climate to agriculture contains 18 references, that on phenology 8.

SOILS-FERTILIZERS.

Soils courses at the Iowa State College, P. E. Brown (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 42-47).—The soils courses at the Iowa State College are briefly outlined and discussed, the five distinct groups now recognized being soil physics, soil fertility, soil bacteriology, soil surveying, and soil management.

Mechanical study of soil, D. J. HISSINK (Indische Mercuur, 38 (1915), No. 47, pp. 975-977).—This is a general statement of the present status of the mechanical classification of soils.

The colloids of clay and humus soils, P. Rohland (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 8-9, pp. 360-367).—This is a second brief contribution to the subject (E. S. R., 32, p. 318).

Experiments on water holding in vegetation pots, P. EHRENBERG, F. BAHB, and O. Nolte (Jour. Landw., 63 (1915), No. 3, pp. 199-225).—Pot culture experiments with corn in sand to test the relative values of various substances for increasing the water-holding capacity of sand in pot culture experiments are reported. The pots contained about 15 kg. of sand; and emery, pulverized glass, and barium sulphate were added in 1 kg. amounts; kieselguhr, artificial zeolite, and clay in amounts of ½ kg.; and peat dust ¼ kg.

The results are taken to indicate that of the materials tested barium sulphate may be used to the best advantage for increasing the water-holding power of sand in sand cultures. Under certain conditions kieselguhr may be used, but emery only in special cases. Powdered glass, artificial glass, clay, and peat are considered unsuited for general use for this purpose.

Miscellaneous samples, soils, L. Heimburger (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 1, pp. 167-174).—This section of the report contains the results of analyses of 21 samples of Florida muck, rock, and calcareous, sandy, forest, and humus soils.

Soil survey of Elkhart County, Indiana, G. B. Jones and R. S. Hesler (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 28, fig. 1, map 1).—This survey, made in cooperation with the Indiana Department of Geology and issued May 25, 1916, deals with the soils of an area of 295,680 acres in northern Indiana, the topography of which is characteristic of a glaciated region and varies from flat to hilly. The soils are of glacial origin and are grouped as upland and sand-plains soils. Exclusive of muck, peat, and meadow, eleven soil types of four series are mapped, of which the Miami loam, Plainfield sandy loam, and Miami sandy loam cover 37, 27, and 12.5 per cent of the area, respectively.

Soil survey of Lafayette Parish, Louisiana, A. H. Meyer and N. M. Kirk (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 32, flg. 1, map 1).—This survey was issued May 22, 1916, and deals with the soils of an area of 176,640 acres in southern Louisiana which lies mostly in the coastal prairie region of the Gulf Coastal Plain province. "By far the greater portion consists of the uplands, or terrace, the surface of which is, for the most part, practically level." In general the drainage is fairly good.

The soils are grouped as upland and first bottom. Excluding muck and swamp, ten soil types of nine series are mapped of which the Oliver, Lintonia, and Crowley silt loams cover 38.6, 25.6, and 11 per cent of the area, respectively.

Soil survey of Ramsey County, Minnesota, W. G. SMITH and N. M. Kirk (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 37, figs. 2, map 1).—This survey, issued May 17, 1916, deals with the soils of an area of 103,040 acres in east-central Minnesota, the surface of which is hilly with intervening areas of level to rolling lands. Drainage is incompletely established over a large part of the county.

The soils are directly or indirectly of glacial origin and are predominantly loams. Including marsh and rock outcrop, 18 soil types of 10 series are mapped, of which the Gloucester loam, Merrimac loamy fine sand, Miami loam, Merrimac loam, and marsh cover, respectively, 16.1, 13.7, 11.3, 11.2, and 10.6 per cent of the area.

Report on the soils of Fiji, I, C. H. WRIGHT (Dept. Agr. Fiji Bul. 9 (1916), pp. 23).—Analyses of two samples of banana soil from Nasinu, three samples of coconut soil from Laucala, two samples of red and two samples of black "soapstone" soil from Suva, four samples of alluvial soil from Navua, and one sample of banana soil from Galoa and one sample of swamp soil from Qaraniqio are reported, together with appendixes giving instructions for taking official and private samples of soil for analysis and instructions for mechanical analysis.

Some Johore soils, J. Grantham (Agr. Bul. Fed. Malay States, 4 (1916), No. 4, pp. 114-121).—Mechanical and chemical analyses of five samples of rubber soils from Johore Bharu, 11 samples of rubber and three samples of coconut soils from Muar, and seven samples of rubber soils from Batu Anam, in Johore, Federated Malay States, are reported.

Studies on nitrogen fixation and Azotobacter forms in soils of foreign countries, C. B. Lipman and P. S. Burgess (Centbl. Bakt. [etc.], 2. Abt., 44 (1915), No. 17-23, pp. 481-511, pl. 1).—Studies of the nonsymbiotic nitrogenfixing flora, especially those of the Azotobacter group, and of the nitrogenfixing powers of the mixed soil flora of 46 soils from Egypt, India, Japan, China, Syria, the Hawaiian Islands, Guatemala, Costa Rica, Spain, Italy, Russia, Mexico, Asia Minor, Canada, Unalaska, Samoa, Australia, Tahiti, Belgium, Queensland, and the Galapagos Islands are reported.

The plan of experiment "consisted in studying the appearance of the cultures obtained from soil inoculation into [Lipman's mannite solution], making a microscopic study of the mixed flora, isolating pure cultures from the mixed flora plated out on mannite agar, studying the morphology of these, and determining the nitrogen-fixing powers in both solutions and soils of those forms which, selected from the large number of pure cultures, were distinctly different from one another."

It was found in the mixed culture experiments that only about one-third of the soils tested contained Azotobacter. "A fixation of 5 mg. of nitrogen per gram of mannite or over occurred in only 20 out of 40 soils. In 16 of these 20 soils Azotobacter organisms were found. . . . Soils from the Mediterranean region when compared with soils from all parts of the world manifest very high nitrogen-fixing powers in mannite solution and bear a vigorous Azotobacter flora. Many of the soils studied had been previously dried in stoppered museum bottles for periods varying from 5 to 20 years, but still manifested vigorous powers at nitrogen fixation. The latter was in many cases as high as and in some much higher than that of many freshly collected soils known to possess notable powers in that direction."

Usually a high nitrogen content seemed to be unfavorable to vigorous nitrogen fixation, although the highest nitrogen fixation of the 46 soils tested was obtained with a soil containing about 0.3 per cent nitrogen. "It is more generally true that high fixations of nitrogen are accomplished by soils in mannite solutions only when Azotobacter organisms form a part of the same flora. . . .

"Many different forms of Azotobacter were observed in those soils possessing that group of organisms. Very frequently one soil showed the presence of two or three different species of Azotobacter. A. chroococcum, however, was the most prominent of all the species and was found most widely distributed in the several soils.

"In a number of cases the amount of pigment produced by the Azotobacter forms was most marked. The organism surpassing all others studied in this respect was a form of A. chroococcum in the poor soil from Sinaloa, Mexico.

"Only about half the soils tested showed notable or vigorous gas formation in mannite solution. Only three of these contained Azotobacter organisms. Sixteen of them were the highly ferruginous and humus soils obtained from various portions of the Hawaiian Islands. Gas formation in mannite solutions inoculated with soil would, therefore, seem to be largely accomplished by clostridium and other rod forms and not by Azotobacter. . . .

"Pigment production by cultures ran almost entirely parallel with Azoto-bacter development in them. Thus the total number of cultures producing pigment was 20, only slightly in excess of the number showing Azotobacter organisms. Of these 20 all but two gave a brown to black pigment. The other two gave a yellow to orange pigment. Twenty-five of the mixed cultures exhibited more or less membrane formation. In nearly all cases the presence of membranes was due to Azotobacter development."

In pure culture studies in mannite solution and sandy soil it was found that on the whole the sandy soil was far superior to the solution as a medium for nitrogen fixation by the several forms of Azotobacter studied, since 17 out of 20 organisms added to the soil in every case more than 3 mg. of nitrogen. The latter was accomplished by only 11 organisms in the case of the mannite solutions. Sixteen out of 20 organisms fixed in every case more than 5 mg. of nitrogen per gram of mannite in the soil as a medium, whereas there were but four such in the case of the mannite solution cultures. There were nearly five times as many of the same organisms which fix 6 mg. or more of nitrogen in the soil culture as there were in the case of the solution cultures.

Studies of the relation of soil type to nitrogen fixation by pure cultures of two types of Azotobacter showed that the fixation of nitrogen by the two organisms tested was notably smaller in the soils which were their natural habitat than in a totally different type of soil. It is concluded "that the soil type . . . is the determinant above all other factors of an organism's power to fix atmospheric nitrogen."

It was further found that considerable difference existed between the powers of different organisms to use certain carbon compounds in nitrogen fixation.

A final study with 56 soils showed the absence of any general law regulating the ratio of nitrogen present in soils to nitrogen fixation by those soils.

Nitrification and total nitrogen as affected by crops, fertilizers, and copper sulphate, C. A. Jensen (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 10-22; abs. in Chem. Abs., 10 (1916), No. 6, pp. 795, 796).—Studies on the changes in nitrification and total nitrogen content of soils under field conditions at Rocky Ford, Colo., during the summers of 1911 and 1912, and on the influence of different cropping and fertilizer treatments on excessive nitrate accumulation in these soils, are reported.

It was found that "the accumulation of nitrates in the soils in the Arkansas River Valley in Colorado . . . in 1910 and 1911 . . . became less in 1912 and 1913. In the work in 1911 mustard appeared to have some effect in checking the accumulation of nitrate in the field. Copper sulphate at the rate of 100 lbs. per acre on fallow was also effective in checking nitrification, reducing the average seasonal accumulation to about 60 per cent of the amount found in

the check plat. Molasses on fallow decreased nitrification about 25 per cent . . . but the molasses-treated plat showed a little more nitrates than the plats cropped to cane and oats. Manure on fallow gave a slightly higher accumulation of nitrates than the fallow check. Waste lime on fallow caused strong nitrate accumulation, being more effective in this regard than any other treatment. In general, active nitrification did not set in until the first part of June. From then until the middle of July it was strongest, and then suddenly decreased and became very feeble until the end of the experiment, August 17, regardless of the field treatments. . . .

"The mustard plat contained less total nitrogen than any of the others. The fallow plats receiving copper sulphate and molasses contained less total nitrogen than the other fallow plats. The fallow plats with waste lime and manure each contained less total nitrogen than the plat fallowed with nothing added. The reverse was true as regards nitrates. In general, there seemed to be an inverse relation between the amounts of nitrates and amounts of total nitrogen. In the work in 1912, in the presence of a vigorously growing beet crop, the only treatments which showed decided increases in nitrification were cyanamid and manure plus ammonium sulphate. Aside from considerable weekly variations, there was not much change in nitrification from the middle of May till the latter part of July, after which the nitrifying activity was very low and remained so until the end of the experiment, August 26.

"Bone meal, superphosphate, waste lime, and dry yard manure decreased the nitrifying activity. Composted manure produced a slightly higher nitrifying activity than did the dry yard manure, but both these plats showed slightly less nitrates than the checks. The total organic nitrogen in the first foot showed a general decrease from the latter part of May to the latter part of August. . . . This decrease was least from the middle of June to the middle of July. There was also a slight loss of organic nitrogen from the second foot during the same period. It is shown that the seasonal loss of organic nitrogen could not be accounted for by the amounts removed in the crop. No correlation could be established between the nitrate content and the total nitrogen. Taking into account the nitrogen applied in the manures and lime, the manured plats lost the most nitrogen, especially those to which ammonium sulphate was added, while the limed plats showed a gain in total nitrogen. The plats receiving cyanamid, phosphatic fertilizers, and nitrate showed a slight gain in total nitrogen over the checks. The total nitrogen content in the second foot was unaffected by the fertilizers applied in the first foot. The nitrifying activity in the second foot was very low."

The use of nodule bacteria for legumes, G. Köck (Die Verwendung von Knöllehenbakterien zu Leguminosen. Vienna: Mitt. Pflanzenschutz Stat., [1915], pp. 4, fig. 1).—Several different experiments on the inoculation of serradella and lupine crops with nodule bacteria are briefly reviewed, the results of which indicated that the serradella usually responded more markedly to treatment than did lupines. The existence of an after-effect of inoculation of the soil was not established. Differences were observed in the results obtained with different types of bacterial culture. It is thought that inoculation is of great importance for certain legumes under German conditions, but that much depends on the condition of the soil and other environmental factors, thus making tests of the process by each farmer advisable to establish its value in a locality.

Recent investigations on the production of plant food in the soil, I, E. J. Russell (Jour. Roy. Hort. Soc., 41 (1915), No. 2, pp. 173-187, figs. 2).—This lecture deals with the physical, chemical, and biological processes involved in

the formation of substances which the plant takes from the soil and utilizes in building up its tissue.

Manurial experiments, G. K. Kelkar (Dept. Agr. Bombay, Ann. Rpt. Expt. Work Surat Agr. Sta., 1913-14, pp. 23-31).—Six years' fertilizer experiments with cotton and sorghum are summarized, the results of which are taken to indicate that barnyard manure may well be replaced by rotted cactus, poudrette, tank mud, town sweepings, and mowra refuse.

Experiments with cotton and sorghum on the residual effect of night soil showed that ten years after application superior results were still obtained. Experiments conducted since 1911 comparing the fertilizing value of night soil and poudrette for cotton and sorghum gave results generally in favor of the night soil. Experiments conducted since 1908 to compare the fertilizing values of sodium nitrate, calcium nitrate, ammonium sulphate, calcium cyanamid, and barnyard manure, when applied to cotton and sorghum at the rate of 10 lbs. of nitrogen per acre, showed that for cotton sodium nitrate and calcium nitrate gave the best results, while for sorghum ammonium sulphate and the other artificial fertilizers gave as good results as sodium nitrate.

Experiments with cotton comparing the fertilizing value of a combination of 80 lbs. of calcium nitrate and 160 lbs. of superphosphate per acre, with and without 2.4 tons of barnyard manure per acre, and with barnyard manure alone applied at the rate of 8 tons per acre, showed that the best results were obtained with the combination of artificial fertilizers without manure. The results with manure alone and with manure and the artificial mixture were approximately equal.

Experiments with cotton and sorghum showed that neither of these crops responded to nitrogenous, phosphatic, or potash fertilization on black cotton soil. Experiments with cotton and sorghum comparing barnyard manure alone, used at the rate of 3 tons per acre, and a combination of 60 lbs. of ammonium sulphate, 224 lbs. of superphosphate, and 1.5 tons of manure per acre with and without 80 lbs. of potassium chlorid per acre, showed that the best results were obtained with cotton with the mixture without potash. The difference in results obtained with the mixture with potash and with manure alone was slight.

Report on field fertilizer experiments at the Bernau moor cultivation station, A. Baumann and H. Paul (Mitt. Deut. Landw. Gesell., 30 (1915), Nos. 42, pp. 627-630; 43, pp. 651-653; 45, pp. 686-688).—The classified results of four years' experiments with nitrogenous, phosphatic, and potash fertilizers, stable manure, green manure, and lime on an upland moor soil deficient in both nutritive constituents and lime are reported. The cropping system consisted of potatoes, followed in the third or fourth year by rye, which was then followed by meadow or pasture.

A half-and-half mixture of 40 per cent potash salt and potassium-magnesium sulphate was the best potash fertilizer used, giving even better results than the 40 per cent potash salt alone. Phonolite meal was unsuitable as a potash fertilizer for this soil. Wolters sodium phosphate gave on the average the best results of the phosphates used, being better than bone precipitate. Of the nitrogenous fertilizers used, sodium nitrate gave the best results, followed in order by calcium nitrate, lime nitrogen, and ammonium sulphate. Of these, ammonium sulphate produced the greatest increase in the starch content of potatoes.

Stable manure used at rates of 300 and 400 kg. per hectare (267 and 356 lbs. per acre) produced greater crop increases than smaller applications of 200 to 300 kg. per hectare. The increases were small, however, as compared to those

by sodium nitrate, and the influence on starch content was not very marked. In the green manuring experiments the best results were obtained when the green matter and roots were used together with sodium nitrate. Better results were obtained with green matter and roots together than with green matter or roots used with sodium nitrate. Liming produced generally favorable results in these soils, although nitrogen assimilation and the starch content of crops were not markedly influenced. The starch content of potatoes was higher when lime was used alone than when used with a basal fertilizer.

Pot culture experiments, 1914, J. A. VOELCKER (Jour. Roy. Agr. Soc. England, 75 (1914), pp. 306-322, pls. 6; Woburn Expt. Sta. Rpt. 1914, pp. 23-39, pls. 6; abs. in Jour. Bd. Agr. [London], 22 (1915), No. 4, pp. 353, 354).—Experiments on the influence of sulphate, phosphate, carbonate, nitrate, and arsenite of copper on wheat in a relatively rich soil are reported. The results are taken to indicate that sulphate of copper has an injurious effect when used in a quantity supplying 0.05 per cent of copper or more, but that 0.02 per cent of copper or less can safely be used in this form and has a slightly stimulating effect. Phosphate of copper has a generally stimulating influence and can be used in quantities supplying up to 0.1 per cent of copper without producing any toxic effect on the plant. Carbonate of copper is nearly as harmful as sulphate of copper when used in quantities approaching 0.1 per cent of copper. With 0.05 per cent the effect is doubtful, but 0.02 per cent or less has, when used in the form of carbonate, a stimulating influence. Nitrate of copper when supplying 0.02 per cent of copper or more is distinctly harmful, but when used in less amounts has a stimulating influence. Arsenite of copper is very harmful, and even so small a quantity as 0.05 per cent of copper in this form may be toxic in its effects.

Experiments on the influence of the phosphate, carbonate, nitrate, sulphate, and chlorid of lead on wheat showed that "in no case was there any sign of injury, although lead had been used up to 0.1 per cent. The general result was to point, on the whole, to a stimulating effect rather than the reverse. This was especially marked with the phosphate series and the nitrate one. With the carbonate and sulphate the results were very similar to the untreated and with the chlorid the straw seemed to be somewhat reduced. . . . Therefore, lead can be used with impunity up to 0.1 per cent with any of the salts employed."

Experiments on the effects of adding lime to a soil rich in magnesia showed "that addition of lime to a soil rich in magnesia is beneficial and can be applied without detriment even to an extent where the lime is double the amount of magnesia present in the soil."

Soil-acidity experiments on soil continuously cropped to barley led to the conclusion "that where soil acidity has gone to the extent that a crop can not be produced, lime as carbonate of lime may advantageously be added to an extent exceeding that required to neutralize the acidity present, but that where acidity may be indicated but a fair crop be still produced, there is no advantage from adding lime as carbonate of lime even to the neutralizing point. Lastly, when no acidity is shown, further liming is thrown away." In no case did the use of calcium carbonate produce the harmful effects produced by caustic lime.

Experiments with mustard, barley, peas, and tomatoes to determine the influence of inoculating soil with Bottomley's peat preparation led to the conclusion that "the peat preparation exercised a distinct influence upon the vegetation. The results with barley, peas, and mustard, coupled with those on the vegetative growth of the tomatoes, clearly show that there is something effected by the peat and that this is due not to the chemical composition alone."

The Illinois system of soil fertility from the standpoint of the practical farmer, Brother Leo (Illinois Sta. Circ. 186 (1916), pp. 3-8).—This is an address before the Illinois Farmers' Institute at Decatur, February 22, 1916, in which a popular discussion of the well-known Illinois system of soil fertility is given together with an account of the successful use of this system on the farm of the University of Notre Dame.

The use of fertilizers in 1916, W. P. Brooks (Massachusetts Sta. Circ. 59 (1915), pp. 8).—This circular gives the substance of the points agreed upon at a conference of the directors of the New York, New Jersey, and New England stations, with the addition in a few cases of conclusions based chiefly upon results of experimental work at the Massachusetts Station.

Growing crops without potash in 1916, C. D. Woods (Maine Sta. Doc. 520 (1915), pp. 15).—This is an address delivered before the Maine Seed Improvement Association, December 8, 1915, which is based in part upon the conclusions reached at a meeting of the directors of the New England, New Jersey, and New York stations and in part on special studies made by the Maine Station.

The action of new nitrogenous fertilizers, Gerlach (Mitt. Deut. Landw. Gesell., 31 (1916), No. 7, pp. 90-93).—Pot experiments with oats and white mustard on weak humus loamy sand and loamy sand, plat experiments with oats, rye, and wheat on loamy sand, and field experiments with beets, barley, and rye on loamy sand and light loamy sand soil are reported, the purpose of which was to determine the relative fertilizing action of sodium nitrate, lime nitrogen, urea, urea nitrate, ammonium sulphate, ammonium chlorid, ammonium bicarbonate, ammonium sodium sulphate, and an organic nitrogenous fertilizer.

It was found that under the favorable conditions existing in the pot experiments, lime nitrogen and urea showed a fertilizing action approximately equal to that of the ammonium and nitrate fertilizers. In the field experiments, and especially on light soils, the opposite was frequently the case. Urea usually gave better results than lime nitrogen. The lime nitrogen gave, in general, relatively unfavorable results and it is thought that field experiments of long duration with it and urea are necessary to determine the conditions for their best utilization. Urea nitrate, while not generally giving the same results as urea, is considered a valuable fertilizer. Ammonium chlorid and ammonium sodium sulphate gave as good results in pot cultures as ammonium sulphate, but the results of field experiments with these two fertilizers were unfavorable. Ammonium bicarbonate did not give as good results as the other fertilizer salts, especially on sand soils. The least favorable results were obtained from the organic fertilizer. No injurious action by any of the fertilizers was observed.

Phosphates and honesty, C. G. Hopkins (Illinois Sta. Circ. 186 (1916), pp. 9-31).—This is an address before the Illinois Farmers' Institute at Decatur, February 22, 1916, consisting of a summary of results of experiments at a number of the state agricultural experiment stations on the use of phosphatic fertilizers from which it is concluded "that where phosphorus is deficient in the soil it must be applied in order to increase and permanently maintain fertility or productive power. At moderate prices either bone meal, acid phosphate, basic slag phosphate, or fine-ground natural rock phosphate may be used with profit. When prices are sufficiently low, the more readily available phosphates are probably best, especially for garden crops or on soils which are deficient in decaying organic matter, or when the cost of raw phosphate is prohibitive; but even for garden crops, and also in beginning soil improvements for general farm crops even before adequate supplies of organic matter can be provided. liberal applications of raw phosphate may well be used when exhorbitant prices are charged for other phosphates."

Certain factors which influence the fertilizing action of the slightly soluble phosphates, H. G. Söderbaum (K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 5, pp. 448-477, figs. 7; Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 112 (1915), pp. 35, figs. 7; abs. in Chem. Abs., 9 (1915), No. 23, p. 3319).—Pot culture experiments with oats, barley. rye, and wheat on soils deficient in both nitrogen and phosphoric acid to determine the influence of the carbonate and sulphate of magnesium, sodium nitrate, ammonium sulphate, and organic nitrogen on the fertilizing action of superphosphate, Thomas slag, dicalcium phosphate, tricalcium phosphate, bone meal, Algerian phosphate, and apatite are reported.

Previous experiments on the influence of lime on the slightly soluble phosphates are reviewed, which showed that while the addition of lime to the readily soluble phosphates had no marked influence upon their fertilizing action, that of the less soluble phosphates was inhibited. With a low lime content in the soil either type of phosphate was used to advantage, but with a high lime content the insoluble phosphates gave no favorable results.

In the present experiments it was found that when using superphosphate a larger crop yield was obtained with ammonium sulphate than with sodium nitrate, but when using tricalcium phosphate the opposite was true. results varied with the crops, wheat being more sensitive than the others. When using dicalcium phosphate little difference was observed in the action of the two nitrogen compounds. With the less soluble phosphates ammonium sulphate and organic nitrogen proved superior to sodium nitrate, except with barley, with which ammonium sulphate and organic nitrogen always gave a poorer crop than sodium nitrate, regardless of the type of phosphate used. When magnesium sulphate was used with the readily soluble phosphates, little influence was observed on crop growth, regardless of the form of nitrogen used, but when magnesium carbonate and ammonium sulphate were used with readily soluble phosphates a distinctly increased yield was obtained. With the less soluble phosphates, magnesium sulphate gave slight and conflicting results, and the results obtained with magnesium carbonate varied with the plant, the yield of rye and wheat being increased and that of barley and oats slightly decreased.

Displacement of the potash and phosphoric-acid contents of certain rocks by some fertilizers, G. André (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 3, pp. 133-136; abs. in Rev. Sci. [Paris], 54 (1916), I, No. 3, p. 94).—Experiments conducted along lines similar to those with feldspar, previously noted (E. S. R., 30, p. 126), are reported in which glauconite containing 7.08 per cent potash was subjected to the action of calcium carbonate, sodium chlorid, sodium carbonate, ammonium sulphate, and calcium sulphate in the presence of water, using 1 gm. of the salts to 10 gm. of glauconite. It was found that the salts in the order mentioned dissolved 3.24, 5.67, 5.62, 7.17, 9.97, and 5.56 per cent of the total potash content of the glauconite. These results are said to be greater than those obtained with feldspar.

In further experiments with apatite, using ammonium carbonate, sodium nitrate, potassium nitrate, and potassium carbonate, it was found that ammonium carbonate and the nitrates failed to displace any appreciable amount of phosphoric acid. Potassium carbonate displaced about 0.35 per cent of the phosphoric-acid content of the apatite.

Feldspar as a possible source of American potash, A. S. Cushman and G. W. Coggeshall (Trans. Amer. Inst. Chem. Engin., 7 (1914), pp. 184-202).—In a second contribution to the subject (E. S. R., 27, p. 724), the authors report additional investigations which were conducted with the idea of separating and

concentrating the soluble potash salts made available by the process previously noted. The process developed has been previously described by Coggeshall (E. S. R., 34, p. 27).

The results of a comparison of the product with imported German muriates are taken to indicate that "without any attempt at fractional separation, muriate of potash may be made from American feldspars equal in character to the usual imported muriates, and that they are as well adapted to be used in commercial mixed fertilizers as those imported." After a further comparison and discussion of costs of plant and operation, it is stated that "if 80 per cent muriate of potash has been heretofore used at a cost in this country of \$37.50 per ton, there is shown a saving by the above process of over \$6 per ton, or 20 per cent profit on the manufacturing cost."

Potash from fir wood mill waste, H. F. Zoller (Jour. Indus. and Engin. Chem., 8 (1916), No. 2, pp. 105-108).—Analyses of Douglas fir and cedar ashes are reported, the results of which, together with other general considerations, are taken to indicate "that it is possible to obtain potash, calculated as K₂O, from Douglas fir mill waste incinerators in the amounts of from 10 to 20 lbs. per ton of 'ash' employed. Furthermore, that this potash may be obtained, along with other extractable matter, by merely leaching the ash in suitable vats with hot water for a 24-hour period and in all probability a 12-hour period would be as efficient."

Potash from kelp: A record of handling kelp in commercial large-scale operation, I. F. LAUCKS (Metallurg. and Chem. Engin., 14 (1916), No. 6, pp. 304-308, figs. 6).—This is a record of a trial of large scale kelp handling operations, confined entirely to the species Nereocystis luetkeana of Puget Sound, including methods and cost of harvesting, transporting, and drying.

It is stated that this type of kelp contains an average of between 92 and 93 per cent water. "The cheapest and most satisfactory type of conveyor is the chain conveyor with wooden flights and either double or single chain. . . . The direct-heat rotary drier appears to be the most satisfactory type."

The composition and use of certain seaweeds, J. HENDRICK (Jour. Bd. Agr. [London], 22 (1916), No. 11, pp. 1095-1107).—A summary of analyses of a large number of samples of the common seaweeds and their ash collected from different points on the coast of Scotland is given. The following table shows the percentages of ash and of potash in the ash of the different seaweeds:

Ash and potash of seaweed.

Kind of seaweed.	Ash in weed as received.			Potash in ash.		
	Maximum.	Minimum.	Average.	Maximum.	Minimum.	Average.
Laminaria digitata: Stems. Fronds. L. stenophylla: Stems. Fronds.	5.22	Per cent. 4.78 3.75 5.56 4.31	Per cent. 6.32 5.66 5.78 4.66	Per cent. 35.62 26.35 39.21 22.03	Per cent. 20.10 16.80 27.07 17.47	Per cent. 28.71 20.99 33.60 20.21
Fucus vesiculosus F. nodosus F. serratus	9.06	4.66 5.52 4.88	6. 53 6. 35 5. 49	20. 82 14. 88 20. 76	12.35 9.47 16.71	15. 29 12. 22 18. 60

The fertilizing action of sodium chlorid, B. Schulze (Landw. Vers. Stat., 86 (1915), No. 5-6. pp. 323-330; abs. in Chem. Zentbl., 1915, II, No. 5, p. 239; Ztschr. Angew. Chem., 28 (1915), No. 65, Referatenteil, p. 421; Jour. Chem. Soc. [London], 108 (1915), No. 634, I, p. 764).—Pot experiments with mustard on a

soil poor in potash and on a mixture of loam soil and sand to determine the extent of the action of common salt in setting free the potash from an artificial potassium zeolite are reported. The results are taken to indicate that common salt solution does not have a solvent effect on potassium zeolites, and that if an increase in crop is obtained by fertilizing with common salt it can not be attributed to the indirect effect of the salt in setting free the potash of potassium zeolites in the soil. It is further concluded that sodium may act directly as a nutritive element for some plants.

Bat fertilizers, C. N. Ageton (Estac. Expt. Agron. [Cuba], Informe An., 3 (1909-1914), pp. 92-97).—Analyses of 37 samples of bat guano from Cuba are reported and discussed.

Notes on the chemical composition of Karroo ash, C. F. Juritz (So. African Jour. Sci., 12 (1915), No. 4, pp. 133-142).—A number of miscellaneous analyses of kraal manure and the burned manure ash from stock-raising districts of South Africa are reported. A summary of analyses of 29 samples of the ash showed average contents of potash 9.85, lime 21.81, and phosphoric acid 2.86 per cent.

Fertilizer analyses, A. J. Patten, O. B. Winter, O. F. Jensen, and E. F. Berger (*Michigan Sta. Bul. 275 (1915*), pp. 3-25).—This bulletin contains the results of actual and guarantied analyses of 358 samples of fertilizers and fertilizing materials representing 300 brands offered for sale in Michigan during 1915. Of these 21 were below guaranty in nitrogen, 19 in available phosphoric acid, 5 in total phosphoric acid, and 33 in potash.

Tabulated analyses of commercial fertilizers and fertilizer materials, J. W. Sample (Tenn. Dept. Agr. Fert. Bul. 1915, pp. 61).—This bulletin contains the results of actual and guarantied analyses of 376 samples of fertilizers and fertilizing materials collected for inspection in Tennessee during 1915, together with general information for farmers on the use of fertilizers and the text of the state fertilizer inspection law.

Commercial fertilizers, inspection 1915, B. H. HITE and F. B. KUNST (West Virginia Sta. Insp. Bul. 4 (1916), pp. 69).—This bulletin contains the results of actual and guarantied analyses of 332 samples of fertilizers and fertilizing materials collected for inspection in West Virginia during 1915, together with a discussion of the fertilizer situation, inspection work, etc.

AGRICULTURAL BOTANY.

Agricultural bacteriology, H. L. RUSSELL and E. G. HASTINGS (Madison, Wis.: H. L. Russell, 1915, pp. VI+304, figs. 48).—The present edition (E. S. R., 22, p. 723) treats of the properties of micro-organisms, soil bacteriology, the relation of micro-organisms to foods, and transmissible diseases. One chapter deals with bacterial diseases of plants.

Determining types of genera, O. F. Cook (Jour. Wash. Acad. Sci., 6 (1916), No. 6, pp. 137-140).—This is a discussion of the need for a stable taxonomy in both branches of biological science and the difficulties to be overcome in working out a practicable system.

Physiological temperature indices for the study of plant growth in relation to climatic conditions, B. E. LIVINGSTON (Physiol. Researches, 1 (1916), No. 8, pp. 399-420, figs. 4; abs. in Science, n. ser., 43 (1916), No. 1106, p. 362).—This publication deals with the derivation and use of a series of physiological indices of temperature efficiency for plant growth, these indices being derived from data obtained by Lehenbauer in a study of the relation of temperature to the elongation rate in seedling maize shoots (E. S. R., 32, p. 334). The system

is said to differ from others in that it is based on actual physiological experimentation, it takes account of the general principle of temperature minima, optima, and maxima, and it shows a much greater rate of increase for the index value with rising temperature between 35.6 and 89.6° F. (2 to 32° C.) than does either of the other systems to which, on whole, it is considered preferable.

By the use of these new indices, physiological summation indices of temperature efficiency for plant growth have been obtained for many stations in the United States, and these have been charted to give a new temperature zone map of the country. It is thought that the physiological system of indices gives the nearest approach yet made to a true expression of the relation of temperature to plant growth.

Acacia seedlings, R. H. Cambage (Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 1, pp. 81-121, pls. 5, figs. 5).—The author gives details obtained by him in the study of species of Acacia as met with in Australia, where members of this genus show various forms and degrees of variation of the several parts, presumably under the influence of the peculiar conditions there prevailing.

Multiple leaves in clover, J. Perreaz (Bul. Soc. Vaud. Sci. Nat., 5. ser., 50 (1914). No. 182, pp. 15-22, fig. 1).—The author concludes a discussion of his observations by stating that the appearance of supplementary leaflets in the different species of clover is due to heredity or to nutritive factors. These may be distinguished, as the latter appear on the same plan as the normal growth while the former appear on a different plan.

Variations in flowers of Iris, R. PIROTTA (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 9, pp. 897, 898).—Discussing the appearance in Iris flowers of flecks, spots, or lines, which in some cases were even showy, varying in form, size, number, and position, or sometimes lacking in successive seasons, the author mentions his more recent observations of other variations, which are as yet incomplete.

On the inheritance of the flowering time in peas and rice, Y. Hoshino (Jour. Col. Agr. Tohoku Imp. Univ., 6 (1915), No. 9, pp. 229-288, pls. 5).—Since 1907 the author has carried on genetical studies with rice and peas, his work bearing upon the theory of a multiple factor.

It is claimed that his experimentation has demonstrated the fixity of the character of flowering time in the original varieties of peas and the presence of two pure lines in the population of one variety. Flowering time in the F_1 generation inclines toward the late parent in peas, toward the early one in rice. The variation range of F_2 families covers the combined range of both parent varieties, but their variation type is not the ordinary one. The inheritance of flowering time follows the Mendelian law in the F_3 and F_4 generations. As an explanation of the inheritance of flowering time in peas, the author suggests the presence of two Mendelian factors which differ in their effects, and gametic contamination caused by hybridization whose nature is not yet explainable. From a study of the variation types in peas, it is thought that the hereditary difference of the two pure lines is qualitative and not quantitative. A correlation is noted between flowering time and flower color in peas, which is thought to be explainable by assuming gametic coupling between the color factor and one of the two factors for flowering time.

A bud variation of the scarlet runner, J. Reinke (Ber. Deut. Bot. Gesell., 33 (1915), No. 7, pp. 324-348).—An account with discussion is given of the appearance in 1913 of a strain of Phaseolus multiflorus, some of the upper inflorescences of which bore white corollas, also further observations upon phases of development and heredity in the progeny.

Amphiclinous hybrids, H. DE VRIES (Ber. Deut. Bot. Gesell., **53** (1915), No. 8, pp. 461-468).—The author has found that the crossing of *Enothera lamarckiana* with *E. lamarckiana nanella* gives, according to cultural conditions, from 0 to 90 per cent of dwarfs in the progeny. The percentage is usually below 50 per cent in the progeny of the first year, but above that figure in that of the second. These figures may be raised by early planting or abundant water supply during the period of root formation. The percentage of dwarfs in the progeny is thus not constant, depending greatly upon cultural conditions.

Recent mutations of Solanum commersonii, Labergerie (Rev. Vit., 48 (1915), No. 1117, pp. 406, 407).—An account is given of the sudden appearance in 1914 of two mutants, which are described, in the progeny of two plants of S. commersonii grown for several years in contact with a domestic variety of potato. The phenomena noted are compared with those reported by Planchon (E. S. R., 28, p. 130) and Heckel (E. S. R., 33, p. 222). It is suggested that solar illumination may be a factor in such cases.

A case of leaf etiolation due to cold, G. GASSNER (Ber. Deut. Bot. Gesell., 33 (1915), No. 8, pp. 478-486, pl. 1).—Studies previously reported by the author, partly in connection with Appel (E. S. R., 19, p. 345), have been followed up with tests of the aftereffects of low temperatures on germinating oats. Plants germinated at from 1 to 2° C., as compared with those sprouted at 5 to 6° or 20°, remained pale and backward in growth under favorable conditions of heat and light.

Experimental production of tuberous growth at the expense of the root in potato, M. Molliard (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 18, pp. 531, 532).—The author produced in potato seedlings grown in tightly closed tubes tuberous development containing starch on the lower part of the stem, apparently at the expense of other portions of the plant. These conditions showed marked contrast with those in plants similarly kept, except that air was freely admitted.

The question of a physiological unity constituted by a leaf with its internode, J. Kuijper (Kuyper) (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 34, pp. 1285-1293, fig. 1).—The question regarding a possible physiological unity constituted by the leaf blade, the leaf sheath, and the internode having arisen in the course of previous work (E. S. R., 34, p. 627), the author has investigated different varieties of sugar cane. From this work he has concluded that the view of a purely local physiological influence in case of a given leaf is not supported by the evidence obtained.

Contributions to the physiology of stomata in Saccharum officinarum, J. Kuijper (Kuyper) (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 44, pp. 1673-1700, pl. 1).—Studies previously noted regarding stomatal structure in sugar cane (E. S. R., 34, p. 628) have been followed up with investigations of the influence on stomatal behavior of light, temperature, and humidity.

It is stated that while direct sunshine is very effective in causing the stomata to open, darkness causes them to close, although in prolonged darkness the stomata sometimes open to a very small but constant degree. In moderate illumination from a clouded sky, the stomata open slowly and slightly as compared with the behavior in strong sunshine, sunny mornings appearing to be valuable from the standpoint of cane culture. When temperatures of from 43 to 45° C. (109.4 to 113° F.) were produced by the absorption of sunshine by the dark cloth covers the stomata were opened by the heat, but when a shelter was provided the stomata closed normally as in darkness. So far as it was possible to ascertain the influence of air humidity free from complication by other factors, a high humidity of the air appears to increase stomatal opening.

The morning rate of penetration is greater than the afternoon rate in every variety, but the hour of closing and the difference between maximum and minimum opening differ with the variety. The author thinks that early closing may be a profitable feature for the plant on account of a more economical water balance.

It is thought that, while many facts referred to periodicity may be explained by the influence of light, temperature, and water content, there are still some indications that after a prolonged period of darkness, the stomata tend to open between 8 and 10 a. m., suggesting a tendency to periodicity.

Observations on transpiration in sugar cane, J. Kuijper (Kuyper) (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 45, pp. 1715-1733, pl. 1, fig. 1).—
The work above reported was followed up with experiments on transpiration in connection with the movements of the stomata and accompanying water loss in sugar cane. Fresh stalks from six to nine months old were cut in the early morning and placed in large bottles of water the surface of which was protected from evaporation by a layer of oil.

Abundant watering of the plants approximately doubled the amount of water ordinarily transpired. The daily course of transpiration in different varieties permits their arrangement into three groups, two of these attaining their maxima respectively in early morning and at 11 o'clock, while those of the third group show very small differences during the whole day. These differences in the utilization of available water are supposed to correspond to differences in production and in resistance to drought.

The daily loss of weight in one variety may double that in another. No connection was established between transpiration rate and stomatal count of leaf area. The maximum transpiration rate may be reached after the stomata have begun to close, the rate of transpiration being in a measure independent of stomatal behavior. Decrease or deprivation of light decreases transpiration. The varietal differences in transpiration rate are thought to be important as giving a new basis for the selection of canes for certain conditions of soil and climate.

Sap ascent, A. Maillefer (Bul. Soc. Vaud. Sci. Nat., 5. ser., 50 (1914), No. 182, pp. 23-30).—It is thought that the amount of energy due to transpiration of water evaporated, 15.1 kilogrammeters per kilogram, is insufficient to account for the observed facts of sap ascent, and that the living cells of the wood must also play a part.

A new theory of gum flow, P. Sorauer (*Ztschr. Pflanzenkrank.*, 25 (1915), Nos. 2, pp. 71–84; 3, pp. 134–154, flgs. 6).—As a result of later studies (E. S. R., 27, p. 851) on the characters and behavior of cells and tissues in plants showing gum flow, the author states that cultivated cherry trees belong to one of those families which show considerable tendency to liquidation of certain portions of their cell membranes due to reactions in various stored substances. This tendency may often be noted in very young branch tips which may show cell deterioration or gummosis. The conditions for gummosis here existing do not necessarily result in its appearance, often having only symptomatic significance and showing on examination merely more or less predisposition thereto.

It appears that gummosis is primarily a condition of local plethora or a storing of material which, on account of its richness in hydrolyzing enzyms, can not develop into normal cell tissue. This condition manifests itself through the coloration of certain cells and may be related in its development to weather and nutritive conditions.

The artificial absorption of liquids by aerial parts of plants, C. Acqua (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 23 (1914), II, No. 3, pp. 78-84).—Experiments are described leading to the conclusion that

plants can easily take up substances in solution, either by means of their leaf surfaces or through cut ends of branches, the latter method entailing comparatively slight injury. While some plants are said to resist for a longer time seasonal or abnormal tendencies under the influence of absorbed solutes, it is thought that no very important alterations of the general condition of the plants can be produced in this way at the present time. It is believed, however, that these methods may be employed in the study of some important agricultural problems.

Albuminous bodies in cells as ergastic substances, A. Meyer (*Ber. Deut. Bot. Gesell.*, 33 (1915), No. 7, pp. 373-379).—This is a preliminary discussion of the author's conception of dissolved or ultramicroscopic substances or bodies as a reserve at the disposal of the working portions of the cells.

The physiological theory of chlorophyll, E. G. Pringsheim (*Ber. Deut. Bot. Gesell.*, 33 (1915), No. 7, pp. 379-385).—This is largely a discussion of the contributions by Iwanowski (E. S. R., 33, p. 824) on a physiological theory of chlorophyll.

Artificial hastening by pressure of water absorption by seeds, H. DE VRIES (Biol. Centbl., 35 (1915), No. 4, pp. 161-176).—On account of the slow and partial germination of the seeds in testing for mutation, involving the danger of loss of possible forms, the author attempted to overcome the difficulty by subjecting the seeds to pressures of from 6 to 8 atmospheres for 2 or 3 days.

It was found that the rate of germination was largely increased, approaching, or in some cases reaching, 100 per cent. It is thought that the effect of pressure is to force the water into the interstices from which it is ordinarily excluded by air spaces or bubbles.

The action of hydrogen ions and some anions on the germinative period of Avena sativa, F. Plate (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 23 (1914), II, No. 5, pp. 166-171).—Reporting studies related to those previously noted (E. S. R., 33, p. 727), and testing the influences of common acids on the growth of A. satira, the author states that both cations and anions exert influences which are chemically and biologically distinct. The hydrogen ion is localized and exerts its influence mainly in the roots, and the anion is localized and exerts its influence in the region of the growing points.

Studies on the influence of the chlorids on the germinative period of Avena sativa, F. Plate (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 23 (1914), II, No. 6, pp. 234–238).—In continuance of the studies reported above, but employing chlorids in solutions of different strengths, the author details the effects thereby produced on growth. An arrangement is made of alkaline nitrates and chlorids in two series according to their observed effects on the total weight of the plant, growth of root, growth of shoot, correlation of development, and atomic weights of the positive elements employed.

It is stated that the kind of anion present has a certain influence upon the action of the cation employed when the action of the latter is not toxic to the plant. If the cation is decidedly toxic, this toxicity is maintained whatever anion may be employed.

Hydrocyanic acid formation in the germination of seeds, III, IV, G. RAVENNA (Atti R. Accad. Lincei, Rend. Cl. Sei. Fis., Mat. e Nat., 5. ser., 23 (1914). II, No. 6, pp. 222-226; 7, pp. 302-306).—In pursuance of reports on studies carried out in connection with others (E. S. R., 24, p. 534; 27, p. 132), the author gives an account of the methods employed and the results obtained in a study of hydrocyanic acid in germinating seeds of Phaseolus lunatus. An augmentation of that component was noted in the early period of germination, but this was followed by a diminution.

Experiments on the physiology of indigo-yielding glucosids, F. R. Par-NELL (Mem. Dept. Agr. India, Bot. Ser., 7 (1915), No. 5, pp. 195-212).—Giving details of a study on parts of several plants, the author states that an indigoyielding glucosid is present in the roots and seeds of Wrightia tinctoria and of W. tomentosa, but not in the leaves of the latter. The glucosid and its enzym in W. tinctoria are distinct from those of Indigofera arrecta and I. sumatrana. The glucosid content in W. tinctoria seed germinated and grown without nitrogen supply increases to about 300 per cent in about 40 days, but it decreases considerably as nitrogen starvation progresses. W. tomentosa seedlings show no appreciable increase of glucosid under like conditions. In cuttings of Polygonum tinctorium and Strobilanthes flaccidifolius grown without nitrogen part of the glucosid disappears, presumably being used up as a nitrogenous reserve. In W. tinctoria and I. arrecta the maximum percentage content occurs very early in the leaf development, the actual amount in any leaf increasing during growth to maturity and then remaining constant until after the leaves fall.

Indican is produced in the dark by etiolated shoots of *I. arrecta*. There is no variation in indican content between night and day in *I. arrecta* and *I. sumatrana*, and no marked change is observable after keeping *I. sumatrana* in the dark for 36 hours.

No definite function is assigned to indigo-yielding glucosids in general or to those of any particular species.

Cytological observations on the mode of formation of anthocyanin pigments in flowers, A. Guilliermond (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 17, pp. 494-497).—Referring to the recent work of Moreau (E. S. R., 33, p. 523) as confirmatory of his own views previously noted (E. S. R., 30, p. 729), the author gives a résumé of the results of his own studies during 1914 and 1915.

It is stated that in the flower of canna, the formation of anthocyanin involves a process identical with that observed in leaflets of rose. Observations on *Pelargonium zonale* and *Iris germanica* are also described. In the latter the formation of anthocyanin presents two phases which are discussed. These studies are held to confirm the conclusion previously reached by the author and by Moreau that anthocyanin is formed in flowers exactly as it is in leaves.

The coloring matters of chromatophores, H. KYLIN (Naturw. Wehnsehr., 31 (1916), No. 7. pp. 97-103, figs. 8).—Noting results of studies on the color constituents in higher plants and algæ, the author discusses their properties and their probable significance in connection with the activities of the plants.

Alkaloid formation in plants.—I, Studies on protein and nicotin content during growth, H. B. RASMUSSEN (Biochem. Ztschr., 69 (1915), No. 5-6, pp. 461-466).—These studies, carried out with Nicotiana rustica and with Hungarian and Virginia varieties of tobacco, show no clear and constant relation between the richness of the fertilizers used and the nicotin content of the resulting plants, but they do show an increase of nicotin with the age and growth of the plants. The total nitrogen varied during growth according to the variety of the plant and the situation of the leaves tested. In the less strongly manured plants, the total protein nitrogen decreased with their age. In the more heavily manured, the autumn content was greater than that of August.

The morning and evening content of mulberry leaves, L. PIGORINI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 23 (1914), II, No. 9, pp. 433-437).—Analyses of mulberry leaves are said to have shown that in sunlight such leaves increase from morning to evening their content of organic

substances, including carbohydrates, fats, and both proteid and nonproteid nitrogenous materials, furnishing thus a greater amount of nutritive matter in the latter part of the day.

Plant enzyms.—IV, Invertase of potato leaves, G. Doby (*Biochem. Ztschr.*, 71 (1915), No. 6, pp. 495-500).—Continuing previous work (E. S. R., 34, p. 428), the author has studied the activity of the enzyms obtained from comminuted potato leaves as found in their expressed juices.

The activity of the enzyms contained in the juices as obtained by hand pressure diminished sensibly after the material had been kept for 24 hours. Those obtained by pressures of 100 and 300 atmospheres showed successively lessened enzym activity. It is considered probable that the decreased activity is due partly to a diminution of the enzyms in the juices obtained at higher pressure, but also perhaps to a rapid breaking down of the enzyms themselves.

A note on the occurrence of urease in legume nodules and other plant parts, M. S. Benjamin (Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 1, pp. 78-80).—The author states that, having detected the presence of an enzym capable of splitting urea in the nodules of Trifolium agrarium, T. minus, Pisum arvense, Vicia desciacarpus, V. sativa, Glycine clandestina, Acacia decurrens, A. falcata, A. juniperina, A. linearis, A. lunata, A. pumila, A. suaveolens, Aotus villosa, Daviesia genistifolia, Lathyrus latifolius, and Cytisus proliferus, but not in those of Medicago sativa, M. denticulata, M. maculata, or Trifolium repens, he has extended his study to other parts of plants. A reaction for the presence of the enzym was given by seeds of Cucumis melo, Cucurbita moschata, and Abrus precatorius. Other plant parts giving a reaction for urease were the ovules and pollen of a Hippeastrum, the tubercles, rootlets, and bulbs of Macrozamia spiralis, and the dried, immature leaves of a Wistaria. The reaction proper to the enzym was obtained from a red and a green alga, and it was particularly pronounced and rapid in case of the lichens Ramulina yemensis, Xanthoria parietina, and Usnea barbata.

Although no conclusions are drawn as to the part played by this enzym in the economy of plants, the fact that it has been detected in parts in which symbiosis occurs and in other parts in which active metabolic changes are doubtless in progress, as in pollen, ovules, young leaves, etc., suggests some correlation between its presence and the processes of elaboration and interchange of nutritive material which must be constantly occurring in the living plant.

A new nitrite-forming organism, N. V. Joshi (*Mem. Dept. Agr. India, Bact. Ser.*, 1 (1915), No. 3, pp. 85-96, pls. 2, fig. 1).—An account is given of the discovery and study of a nitrite-forming organism, with an outline of its reactions to temperature, chemical agents, and nutrient preparations.

The influence of ultraviolet rays on reproductive organs of plants, L. Montemartini (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 9 (1911), pp. 13-23).—In these experiments, carried out with several plants named, the author was not able to discover any specific action of ultraviolet rays on the reproductive organs of the plants tested.

FIELD CROPS.

Experiments on the influence of selection, C. Fruwirth (Ztschr. Pflanzenzücht., 3 (1915), Nos. 2, p. 173; 4, pp. 395-451, figs. 5).—The experiments here described were conducted with white mustard (Sinapis alba), oats, and certain leguminous plants.

The results obtained with six Johannsen lines of white mustard, producing yellow and brown seeds and sometimes both kinds on the same plant, showed

that continuous selection of either the yellow or the brown seeded forms failed to establish pure transmission of the seed color. It was further found that self-pollination of mustard can take place and that self-pollination continued several generations does not reduce the yield of seed or give rise to weak plants. Crossing a pure yellow-seeded form with a brown-seeded plant of one of the lines studied indicated that xenia in the yellow-seeded mother plant may show itself in the form of a browning of the seed coat. Such a cross also showed a different behavior in the F_1 and a different segregation in later generations than the cross of pure yellow-seeded with pure brown-seeded mustard.

Experiments were conducted with oats to determine whether individual Johannsen lines may be permanently distinguishable from each other by means of the hairs and awns of the outer or lower grains in the spikelets, the color of the glumes of these grains, or the number of grains per spikelet, even when selection in opposition to the line characters is practiced. After the constancy of the line character had become apparent, a comparison of a number of morphologically uniform lines was made to establish whether the relative heritability of characters finds expression each year or only in the average of several years. Finally, studies were made to determine whether seasonal conditions had a definite influence on the characters under observation. The work was begun with four plants grown from grains taken in 1906 from seed of Sechsamt oats.

The observations made on a series of external characters indicated without exception that in a Johannsen line definitely directed selection, even if carried through a comparatively large number of generations, does not modify the line character. The different characters studied were the varying degree of development of the highly modifiable coloring of the seed coat, the interchange between two colors of the seed coat as exhibited in subvarieties of mustard, and the variable development of the very strongly modifiable external characters of hairiness, the presence of awns in the outer grains of oats, and the number of grains produced per spikelet in oats. A number of cases of spontaneous qualitative variation which appeared after a varying number of generations had been self-pollinated are reported.

From the results of the breeding investigations it was concluded that certain external characters, such as those mentioned above as having been the subject of these studies, can not be brought, even by means of continued self-pollination and selection, to a more definite, permanent, and stronger expression. It is stated that the Johannsen lines in question belong to form groups which either show the several characters with different degrees of modification or, as in the case of the mustard lines, represent subvarieties. The statement is made that seed production in the field is more difficult when the particular form group has such highly variable external characters as some of the Johannsen lines of legumes and oats here studied. It is believed that the value of continuing selection with self-pollinated plants was further brought out by the possibility of spontaneous qualitative variations as shown in these experiments, as well as by the fact that certain branches of a Johannsen line may exhibit a difference in growth for several years. Spontaneous quantitative variations were not observed in any of the lines under experiment.

[Work with field crops], A. Boss (Minnesota Sta. Rpt. 1915, pp. 35, 36).— The activities of the sections of farm crops and of plant breeding are briefly noted.

Experiments with different grades of seed oats are reported as showing that the heavier seed gave the larger increased return for the labor of preparation, and that for certain varieties of oats thick seeding seemed to be an advantage. Minnesota No. 261, an early variety selected from the Kherson, outyielded the medium early varieties of oats in the season's trials. In seeding tests with wheat, 1.75 bu. of seed per acre yielded 2.2 bu. more than seeding 1.25 bu., the common rate of drilling.

The results of forage crop studies indicated that as good stands of alfalfa were secured where nurse crops were used as where the crop was sown alone. July seeding, when no nurse crop was used, resulted in the best stands and in the best yields the following year, as compared with seeding in August after potatoes or barley. Inoculation increased the yield and gave a product richer in protein. The soil transfer method of inoculating gave somewhat better results than the use of commercial cultures, and the application of lime gave a definite increase in yield.

Sudan grass gave an average yield of 3.36 tons per acre, and where cut for seed, 700 lbs. of seed were secured. The best yield of hay was obtained by drilling 24 lbs. of seed per acre on June 15 and the best yield of seed by sowing 40 lbs. of seed with a grain drill on May 15.

Experiments with sweet clover pointed out the value of inoculation and the use of lime. Inoculation by transfer of sweet clover soil and the addition of lime gave a much larger yield than inoculation with sweet clover soil without lime or inoculation with alfalfa soil with lime. Where no treatment was given the yield was comparatively small.

Data accumulated in the continued selection of wheat for 14 years, with the object of shortening the stem between the head and the upper leaf for the purpose of decreasing the amount of surface exposed to rust, are reported as showing no progressive effect. The results of corn-breeding work during the year indicated little correlation between earliness of germination and time of maturity and no appreciable correlation between the rapidity of germination of seed of the same ears tested under different temperatures.

[Work with field crops], W. G. TAGGART, A. P. KERR, J. B. GARRETT, and F. C. Quereau (Louisiana Stas. Rpt. 1915, pp. 8-11, 15-17, 27, 28, 29, 30-32).--At the Sugar Experiment Station a complete fertilizer containing 90 lbs. of sulphate of potash per acre gave an increase over check plats fertilized with equal amounts of nitrogen and phosphoric acid, but without potash, of 3.03, 3.55, and 1.73 tons of sugar cane per acre. A comparative test of nitrogenous fertilizers showed that calcium cyanamid ranked close to nitrate of soda and sulphate of ammonia. Calcium nitrate did not prove so satisfactory on sugar cane as on corn. A mixture of 500 lbs. of cotton-seed meal and 250 lbs. of acid phosphate per acre gave an increase of 2.7 tons of sugar cane, and a mixture of 500 lbs, of cotton-seed meal and 500 lbs, of acid phosphate an increase of 8.9 tons, as compared with no fertilizer treatment. A similar experiment in which tankage was used as the source of nitrogen gave an increase of 1.4 tons in the first place and 8.4 tons in the second. These results represent the average of four years. The use of 1.5 in, of water applied in irrigating sugar cane on April 28, May 17, and May 26, produced an increase of 7.6 tons of cane over an unirrigated check plat.

The propagation of new varieties of sugar cane showed that seedling L 511 made a good growth and contained 14.9 per cent of sucrose in the juice, or from 4.5 to 5 per cent more than the juice of cane grown generally. The next seedling in order of value was L 231, and, in addition to this, there were six others giving promising results.

The development of a white flint corn similar to Yellow Creole, which was found in variety tests to be the most suitable to local conditions as a general field crop, is reported. Corn fertilized before planting yielded 49.85 bu., while

corn receiving the fertilizer application after planting yielded 51.45 bu. per acre. Velvet beans proved a little better than cowpeas and soy beans for green manures. The results of experiments with corn indicated that bagasse had no value as a fertilizer. Other fertilizer experiments with corn indicated clearly the responsive power of stiff soils to pea-vine fallow and the use of nitrogenous fertilizers. Alfalfa produced 8.6 tons of hay per acre. Kudzu yielded a large quantity of forage and gave evidence of its value for smothering out Johnson grass.

A brief summary of the work at the State Station points out that a mixture of corn and soy beans, among the different crops tested, gave the best silage. The results of culture tests indicated that there was practically no difference in yield from the application of all of the fertilizer before planting, all during cultivation, or half before planting and half during the cultivation. Removing suckers from corn slightly increased the yield but not sufficiently to compensate for the labor. A plat where cowpeas were planted with corn when laid by, followed by a crop of clover in the fall with a light application of stable manure every three years, produced about five times as much corn as a plat receiving the same cultivation without the manurial treatment. Green manuring with red clover seemed to give as large a yield of corn as green manuring and an application of phosphate and lime in addition. Of 20 varieties of corn tested, Calhoun Red Cob and Yellow Creole were among those giving the best results in yield and in keeping qualities.

Among the forage crops tested, Sudan grass proved promising. It was found best to sow this grass at the rate of 20 lbs. per acre about April 1 in the locality of the station. The growth of ramie is reported as very successful.

At the North Louisiana Station rock phosphate and velvet beans have proved slightly inferior to acid phosphate in the production of both corn and cotton. The use of 315 lbs. of equal parts of cotton-seed meal and acid phosphate as a fertilizer for Sudan grass trebled the yield as compared with the yield of plats receiving no fertilizer. In a test of 18 varieties of cowpeas, Whippoorwill, Groit, New Era, and Brabham, proved superior. The yields of 14 varieties of soy beans varied from a little over 3 to 20.5 bu. per acre, Hollybrook being the leading variety. Of 13 crops, the rank-growing sorghums, particularly Honey sorghum, produced the heaviest tonnage of silage and soiling material. The maximum yield secured was a little over 34 tons per acre on good, red, sandy loam soil fertilized with 200 lbs. of cotton-seed meal and acid phosphate per acre.

The highest yielding varieties of sweet potatoes under test were Doody Yam, Jersey Yellow, and Southern Queen. Twelve fertilizer experiments with sweet potatoes did not give results with a degree of uniformity to warrant conclusions. It is reported that in a sweet potato storage house sweet potatoes were kept in good condition with very small loss.

In 42 tests in thinning cotton, uniformly better results have been secured by following the usual practices.

Plats under a 2, 3, and 4 year rotation experiment at the Rice Station gave an average yield of 17.6 barrels of rice per acre, while the check plats continuously in rice yielded 2.18 barrels per acre of pure red rice. Corn and oats were included in the rotation, and it is believed that rotations including upland crops should be of long duration and that under such a system several profitable crops of rice may be grown in succession.

The use of 200 lbs. acid phosphate per acre has produced the most profitable rice crops for five years in succession. Potash salts have not shown any appreciable increase in yield. Readily available forms of nitrogen were inferior

to organic forms for Honduras rice, but for late maturing varieties the differences were not great.

The Mungo bean appeared to make a heavier growth of vine than any other leguminous crop grown at the station. Garlic also seemed to do well on rice soils.

Suggestions for the use of fertilizers for tobacco and onions for 1916, H. D. HASKINS (Massachusetts Sta. Circ. 60 (1916), pp. 4).—A brief popular discussion of the use of fertilizers for tobacco and onions, suggesting for each crop two fertilizer formulas and noting the value of the use of lime.

Corn in Montana, A. Atkinson and M. L. Wilson (Montana Sta. Bul. 107 (1915), pp. 11-128, figs. 34).—This bulletin discusses the economic importance of corn for Montana, reviews its history from its earliest culture by the Indians down to the present day, presents notes on the classification and varietal history of corn, describes a list of varieties adapted to certain regions of the State, and points out the influence of the prevailing climatic conditions on the production of the crop.

The results of experiments conducted in 1913 and 1914 at Wibaux, where the conditions of eastern Montana are fairly well represented, are reported in tables and discussed. Seven varieties of flint were found to have an average total leaf area per plant of 1,868.6 sq. in., 2 varieties of late flint of 2,124.4, 3 varieties of semident of 1,211, 6 varieties of early dent of 1,119.4, and 2 varieties of late dent 2,101.6 and 4,678.2 sq. in., respectively. The average length of stalk was 47.6 in, in the early flint, 70.1 in, in the semident, and 62.6 in, in the early dent varieties. No great variation was observed in the lengths of the first two or three internodes of any of the groups. Of the stalks studied the early flint varieties had from 6 to 9 internodes, the semident 8 to 11, and the early dent 9 to 10. In the early flint group the internodes were also much shorter than in the other groups. The early flint, early dent, and semident groups had about the same shelling percentage, which varied from 70 to 80 per cent. The proportions of coarse and fine stalk, shelled corn, and cob were determined and are reported in a table. The results of variety tests at Wibaux and at the Huntley substation are also tabulated.

Corn: Varieties, ear-row, and limiting factor tests, W. L. HUTCHINSON (South Carolina Sta. Bul. 186 (1916), pp. 14).—The results of variety and ear-to-row tests conducted at the station and the Pee Dee substation are tabulated. Data secured in fertilizer and culture tests made at the Pee Dee substation in 1914 and 1915 are also reported.

In 1913 the yields of 27 varieties at the station ranged from 28.3 to 49 bu. per acre, Surecropper being the leading variety, and in 1915 the yields of 9 varieties ranged from 24.5 to 37.5 bu., Coker Williamson being the leading sort. At the Pee Dee substation No. 181, among 20 varieties, stood first in yield in 1914 with 52.7 bu. per acre, and Chappell Garric, among 17 varieties in 1915, with 52.1 bu.

Ear-to-row tests at the station in 1913 indicated differences in yielding capacity ranging from 27.7 to 77.7 bu. per acre, and in 1915 from 5.2 to 59.7 bu. At the Pee Dee substation in a similar test in 1914, the lowest producing ear yielded at the rate of 24.3 and the highest at the rate of 50.3 bu. per acre.

The results secured in the fertilizer tests led to the conclusion that nitrogen is the element most needed under the conditions of the test. The culture tests indicated that the method of planting corn in the water furrow between beds and applying all fertilizers to the growing crop may have some merit. A plat treated in this way yielded at the rate of 48 bu. per acre, or more than any one of four other methods of culture under experiment.

Field corn in western Washington, E. B. STOOKEY (Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 2, pp. 7-9).—The possibility of growing corn in western Washington is discussed and some of the experimental work with corn by the substation is briefly noted. Conclusions based on general observations, as well as the results of experiments, are presented, and Minnesota No. 13, Rutherford Dent, Pearsall Dent, Northwestern Smoky Dent, Windus White Dent, and King Phillip are described with reference to their adaptability to the conditions and needs of the region.

Wilt-resistant varieties of cotton, E. F. CAUTHEN (Alabama Col. Sta. Bul. 189 (1916), pp. 67-88, pl. 1, fig. 1).—Tests made of wilt-resistant varieties of cotton in cooperation with farmers having suitable lands are reported, and notes are given on the nature of cotton wilt and on methods of controlling the disease. The wilt-resistant varieties, Dillon, Modella, Cook, Wood, Covington-Toole, Wilt-Resistant, Tri-Cook, Cook 307-6, Dixie, and Dix-Afifi, used in the experiment, are briefly described.

A comparison of the different varieties tested, based on the value of lint and seed per acre as indicated by the average results of 15 experiments, showed the following total values per acre: Cook, nonresistant strain, \$26.78; Modella, \$28.96; Wood, \$33.09; Dixie, \$33.22; Cook 307-6, \$34.17; Covington-Toole, \$34.42; and Tri-Cook, \$40.53 per acre. The range of gains from resistant varieties extended from 8.1 per cent with Wood to 51.3 per cent with Tri-Cook. The average percentage of loss of plants from wilt in these tests was as follows: Cook, nonresistant strain, 40.3; Wood, 15.1; Modella, 14.7; Covington-Toole, 10.5; Cook 307-6, 9.3; Dixie, 8.5; Tri-Cook, 7.3; and Dillon, 5.4 per cent. Dix-Afifi lost no plants in the two experiments in which it was planted.

It is pointed out that these wilt-resistant varieties differ slightly in their relative earliness and that they are somewhat later in the time of opening than such standard varieties as Cleveland, Cook, and Triumph. Among the resistant varieties tested those ranking highest in total money value of seed and lint per acre were the earliest and turned out about 40 per cent of lint.

Methods and results of breeding flax, L. ALTHAUZEN (ALTHAUSEN) (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 1, pp. 12-53, figs. 12).—This article describes the methods of flax breeding employed by the agricultural chemical laboratory at St. Petersburg, together with the principles on which they are based. The work is planned to bring practical results in a short time and at a low expenditure of cost and effort. Some of the more general results are briefly noted.

It is pointed out that from a single selection made in 1909 there were obtained from the same variety seven different forms, among them one presenting with other characters an average length of stem of 80.6 cm. (31.4 in.) up to the point of branching and another with only 47.9 cm. as the corresponding figure. Selections made in 1911 of 24 commonly grown varieties of flax and propagated for two generations showed that these varieties represented a mixture of forms. The isolation of forms not only exhibited marked differences in height of plant, length of stem, and similar readily recognizable characters, but also variations in the color and size of the blossoms and other minor or less apparent qualities. One of the forms isolated had an average blossom diameter of 1.95 cm. as compared with 1.79 cm. and 1.67 cm. for a common variety grown as a check and a small blossomed form, respectively.

Natal grass, a southern perennial hay crop, S. M. Tracy (U. S. Dept. Agr., Farmers' Bul. 726 (1916), pp. 16, figs. 4).—Historical, descriptive, and cultural notes are given on Natal grass, and its value and uses are set forth. An analysis of Natar grass hay is included.

Field peas, N. S. Robb (Idaho Sta. Circ. 2 (1916), pp. 8, fg. 1).—A brief popular account discussing the adaptation of field peas to climate and soil, the principal varieties, and the culture and uses of the crop.

Effect of climatic factors on the hydrocyanic-acid content of sorghum, J. J. Willaman and R. M. West (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 7, pp. 261–272, figs. 4).—The experiments here described were in continuation of work previously noted (E. S. R., 33, p. 234), and were conducted by the Minnesota Experiment Station in 1915 to study the effect of climatic conditions on the amount of glucosid in the sorghum plant. For this purpose two varieties of sorghum, Southern Cane and Early Amber, were grown on plats in Minnesota, Utah, Kansas, and South Dakota, under widely different climatic and cultural conditions. The results are presented graphically and in their discussion the factors which might have any bearing on the cause of the variations in cyanid content or throw any light on the function of the glucosid dhurrin in sorghum are specially considered.

The amount of dhurrin in each plant was found to vary considerably. unhealthy condition of plants, from whatever cause, was usually associated with a higher hydrocyanic-acid content than was found in healthy plants. It is thought possible that under such conditions the plant produces more glucosid for the sake of the stimulating hormones in it. The apparent effect of humidity and temperature on the amount of cyanid in sorghum is considered as probably due to the indirect effect on the rate of growth. Adequate water supply was usually accompanied by a low and inadequate by a high cyanic acid content. It is believed that this is probably due to the need of glucosid stimulation when the water supply becomes low. The character of the growth of the plant is reported as affecting the distribution of dhurrin between leaves and stalks. There was found a proportionately smaller amount in the thick heavy stalks than in the slender ones. It is stated that there is no consistent daily variation in the amount of dhurrin, and that this argues against the functioning of this glucosid as a food storage. The Southern Cane in every plat but one had a higher content of hydrocyanic acid than the Early Amber, and it is concluded that varietal difference is probably of more weight in determining the amount of hydrocyanic acid in sorghum than are the conditions of growth.

Nitrogen content of the wheat of the Transvolga region, N. Tulaikov (Tulajkow) (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 1, pp. 1-11).—Results of analyses made during the four years beginning with 1910 by the experiment station at Besentschuk showed that the nitrogen content of hard and soft wheats from this region was about the same, and that the average nitrogen content of the hard and soft wheats grown in 1911 in the various districts of the government of Ssamara was the same. The grain of different botanical subvarieties of spring wheat grown under the same conditions of soil and climate showed no differences in the content of total nitrogen. It is stated that variations in the nitrogen content of wheat of the harvest of a particular year and produced under identical climatic conditions must be attributed to differences in the chemical composition and osmotic pressure of the soil solution, as botanical differences have no influence in this connection.

Further observations on combating weeds with kainit, T. Remy and J. Vasters (*Landw. Jahrb.*, 48 (1915), No. 1, pp. 137-169, pls. 4).—The effect of applying kainit, calcium cyanamid, and iron sulphate in controlling ragwort, cornflower, wild poppy, wild radish, coltsfoot, wild mustard, Canada thistle, sour thistle, and colchicum was observed in field and pot experiments.

The results confirmed the conclusions drawn from previous work, and brought out again the value of kainit in the control of weeds, especially wild mustard,

wild radish, and cornflower. Kainit was most effective when brought in contact with the plants when these were in the initial stages of development. It was not found desirable to delay the application beyond the appearance of the first flower buds of the weeds studied. The best results with reference to injuring the weeds and benefiting the crop were secured when application was made at the time the grain plants began to stool. It is pointed out that fertilizing with kainit before seeding is frequently of greater benefit to the weeds than to the crop, especially so in the case of rye fields infested with cornflower.

The statement is made that if the use of kainit is to be satisfactorily effective an adequate quantity must be applied when the plants are wet from dew or rain and the kainit solution must remain active on the parts of the plants above ground for a sufficient length of time. For weed control the use of about 1,300 lbs. of kainit per acre is recommended.

Iron sulphate and calcium cyanamid were generally less effective than kainit. The wild poppy proved most sensitive to calcium cyanamid, and in these tests a mixture of 668 lbs. of kainit and 67 lbs. of calcium cyanamid per acre proved more injurious to cornflower than double the quantity of each substance when applied alone.

HORTICULTURE.

The present status of vegetable breeding, E. von Tschermak (Ztschr. Pflanzenzücht., 4 (1916), No. 1, pp. 65-104).—The more important results of breeding investigations with different kinds of vegetables are reviewed. A bibliography of cited literature is included.

Fertilizer experiments with various vegetables on low moor land, Alves (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 33 (1915), No. 13, pp. 287-292).—Fertilizer experiments with different kinds of vegetables conducted in 1914 under the direction of the German Society for the Promotion of Horticulture and the Association of German Vegetable Growers are reported.

Vegetable tests on sandy soil at the Umatilla Experiment Farm, R. W. Allen (Oregon Sta. Bul. 136 (1916), pp. 3-38, figs. 9).—This bulletin presents the results of variety and cultural tests of various vegetables conducted during the past six years. The subject matter is presented under two general crop divisions, namely, important vegetable crops and minor truck crops, the latter crops being poorly adapted to the district or of only secondary commercial importance. Included in the crops which are promising on account of their production and marketing possibilities are asparagus, eggplant, muskmelons, onions, parsnips, peas, potatoes, sweet corn, and watermelons.

The vegetable garden in New Hampshire, J. B. Scherrer (N. H. Col. Ext. Bul. 6 (1916), pp. 42, figs. 20).—The principles of vegetable gardening are here considered with special reference to their adaptation to the home garden and the small commercial garden.

Vegetable growing (Mass. [Bd.] Agr. Bul. 5, 2. ed., rev. (1916), pp. 185, pls. 15, figs. 14).—Some of the articles in the previous edition of this bulletin (E. S. R., 26, p. 539) have been superseded by new ones and a number of other new articles relating to vegetable growing have been added. The subject matter as a whole has been thoroughly revised and brought up to date.

Specific chemical and structural variations caused by grafting the tomato on the cabbage, L. Daniel (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 11, pp. 397-399).—The variations here described consist of the development of granular cellules containing oxalate of lime in the cabbage and the occurrence in the cabbage throughout the region of the union of a well-developed internal medulary liber similar to that of the tomato,

The fruiting relations of various garden forms of Brassica oleracea, T. Roemer (Ztschr. Pflanzenzücht., 4 (1916), No. 1, pp. 125-141).—The results are given of self and cross pollination experiments conducted in 1914 and 1915 with kale, kohl-rabi, Brussels sprouts, and cabbage.

Things to be emphasized in present day horticulture, U. P. Hedrick (N. Y. Dept. Agr. Bul. 74 (1915), pp. 2489-2501).—A review of some results of experiment station work. Among the subjects considered are fertilizer experiments with apples, improving old varieties of fruits, cultural tests of European grapes, fruits resistant to insects and fungi, fruit stocks, methods of improving size, quality, and color in apples, and profits from an apple orchard.

Fruit growing in Spain, G. Fernández de la Rosa (Bol. Agr. Téc. y Econ., 7 (1915), Nos. 80, pp. 733-742; 81, pp. 813-822; 82-83, pp. 921-939; 84, pp. 1013-1021).—An economic study of the fruit industry in Spain with reference to its history, present status, and factors influencing its future development.

The sorting, sizing, packing, and storing of fruit, E. L. MARKELL (*Trans. Peninsula Hort. Soc.* [Del.], 29 (1916), pp. 41-47).—A popular paper on the handling and storing of apples in which some of the results are given of storage investigations conducted by the U. S. Department of Agriculture.

The act relating to the standardization of fruit packing, G. P. Weldon (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 4, pp. 125-128).—The text is given of the California fruit-packing act which went into effect August 9, 1915.

Recent developments in sulphur sprays, J. P. Stewart (*Trans. Ill. Hort. Soc., n. ser.*, 49 (1915), pp. 186-198).—In this paper the author gives special attention to the character of the materials used in sulphur preparations intended for spraying purposes.

Results of spraying experiments for 1915, Neoga station, Cumberland County, O. S. Watkins (*Trans. Ill. Hort. Soc., n. ser., 49* (1915), pp. 202-221).—In continuation of previous experiments conducted at Neoga (E. S. R., 35, p. 39), experiments were conducted in two orchards in 1915. The chief lines of investigation included tests of several proprietary sprays in comparison with Bordeaux mixture and lime-sulphur-arsenate of lead, a comparative test of several brands of arsenate of lead, tests of the effect of special sprays against codling moth infestation as applied at various times throughout the season, a comparison of certain standard nozzles, and a test of a dusting machine and dust sprays. The data secured are presented in tabular form and discussed.

In view of seasonal conditions the results as a whole were not favorable for drawing definite conclusions. The following conclusions, however, appear to hold good in any season. Blackleaf 40 should not be used with arsenate of lead without Bordeaux mixture or lime-sulphur, as it dwarfs the fruit. Niagara soluble sulphur in combination with arsenate of lead should not be used on apple trees, as the trees thus far sprayed with this combination have been seriously injured.

Intercropping the young orchard: From an economic standpoint, M. C. Burrit (N. Y. Dept. Agr. Bul. 74 (1915), pp. 2502-2511, fig. 1).—A discussion of the cost of production in orcharding, with special reference to the use of intercrops to reduce this cost. Data are given showing the economic results of intercropping as practiced in the author's orchards.

Report of the horticulturist, A. G. Turney (Rpt. Agr. New Brunswick, 1915, pp. 100-114, pls. 2).—A progress report on the work of the horticultural division for the year 1915, including data on the cost of operations and returns secured in some demonstration apple orchards.

In view of the prevalence of apple scab in one orchard of 45-year-old Fameuse trees it was decided to top-work the trees to some other variety. Records were

kept and are here given showing the cost of top-working, as well as the amount of fruit harvested from top-worked trees as compared with similar ungrafted Fameuse trees. The total cost for one season in top-working these trees to another variety was \$1.215 per tree.

An experiment was undertaken to determine whether apple scab could be controlled to any extent by removing and destroying the affected twigs before the spores had a chance to germinate. The trees received the usual spraying. The results, although not conclusive, indicate that the removal of the twigs does aid in checking the scab. In the three previous years the trees had been sprayed thoroughly without producing any marked improvement, whereas in the present season they produced nearly all clean fruit in one of the worst scab seasons for years. A similar experiment in removing and burning the fallen leaves early in the spring indicates that this practice is also successful in checking the scab.

The cherries of Japan, E. H. Wilson (*Pubs. Arnold Arboretum*, No. 7 (1916), pp. XIV+68, pls. 8).—This comprises an enumeration and description of the Japanese species of cherries. The work is based upon investigations conducted by the author in Japan, including studies of collected material and material preserved in the herbarium of the Imperial Botanic Garden, Tokyo.

Peach spraying experiments, 1915, Walter White orchard, near Centralia, Ill., O. S. Watkins (*Trans. Ill. Hort. Soc.*, n. ser., 49 (1915), pp. 198-202).— Tabular data are given showing the value of different sprays used on a two-acre peach orchard at Centralia in 1915. The test included a number of brands of arsenate of lead, soluble sulphur, copper ferrocyanid, commercial lime-sulphur, and dust spray.

The grape industry in California (Cal. State Bd. Vit. Comrs. Bul. 6 (1916), pp. 13).—A statistical review of the grape, wine, and raisin industry in California for the year 1915, including some comparative data for 1914. A table is also given showing carload shipments of deciduous fruits.

Report of the National Congress of Viticulture, held at Pamplona, Spain, July, 1912 (Mem. Gen. Ses. Cong. Nac. Vit., 1912, pp. XXXIX+559, pls. 5, figs. 19).—This comprises a general account of the sessions of the National Congress of Viticulture at Pamplona, Spain, in July, 1912, together with the papers, some 50 in number, presented at the congress.

The more important themes discussed include methods of combating various insect pests and diseases; protection of vineyards from late frosts and other climatic disturbances; marketing problems; the culture of grapes in connection with other crops; the reconstitution of phylloxera-infested vineyards, including observations on various American stocks; direct-bearing grapes and hybrid direct-bearing grapes; adaptation of varieties to different types of soil; fertilizers; methods of pruning; methods of preparing and conserving wines; and methods of preventing the falsification of wines. Although the majority of the papers relate to Spanish conditions, a number of papers by French viticulturists and viticultural investigators were presented, together with papers on the viticultural industries in Hungary, Argentina, Chile, and Uruguay.

Grape growing in the Nasik District, H. V. Gole (Dept. Agr. Bombay Bul. 71 (1915), pp. 25, pls. 5).—A practical treatise on grape growing in the Nasik District, India, the subject matter being based largely on the author's experience in growing Vinifera grapes.

Renewing old citrus trees, A. D. Shamel (Cal. Citrogr., 1 (1916), No. 7, pp. 2, 3, fig. 1).—The author cites the beneficial results secured as to yield and quality of fruit when old apple trees are severely cut back. Attention is then called to the practice employed in Bahia navel orange groves in which the trees after 20 to 25 years begin to lose their power of producing profitable

crops. The old tops are removed at this period and new ones grown. It is claimed by the growers that the renewed trees produce larger and better fruits than the original bore at any time. A study of the performance records of the renewed trees appeared to confirm the statements of the growers. Special attention is called to the desirability of studying the effect of renewal of old mayel trees in California in conjunction with the maintenance of individual tree records with reference to the time of pruning, the cultural treatments, amount of fruit produced, etc.

Ribbed Valencia sport, H. J. Webber (Cal. Citrogr., 1 (1916), No. 7, p. 3, fig. 1).—A description with illustrations is given of a variation of the Valencia orange in which the fruit is ribbed.

Preliminary results on budding and grafting experiments with cacao, H. VAN GENT (Meded. Cultuurtuin [Buitenzorg], No. 5 (1915), pp. 9, pls. 5).—Budding and grafting experiments conducted in the Buitenzorg gardens are reported.

Method in manurial experiments with trees (Agr. News [Barbados], 15 (1916), No. 366, pp. 145-147).—A brief description of methods employed in manurial experiments with coconuts and cacao trees in the West Indies and British Guiana.

Manurial experiments on coconuts, 1914-15, J. DE VERTEUIL (Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 2, pp. 56-66, pls. 3).—This report deals with the fourth year's results of manurial experiments with coconuts being conducted under the direction of the Trinidad Board of Agriculture (E. S. R., 32, p. 236).

Coconut experiments, C. H. Knowles (Dept. Agr. Fiji Bul. 8 (1915), pp. 6, pls. 2).—An outline is given of selection experiments with coconuts being conducted on Viti Levu, Fiji, including notes on the methods used in selecting seed nuts and brief descriptions of the varieties selected.

Germinating coconuts, O. F. Cook and C. B. Doyle (Jour. Heredity, 7 (1916), No. 4, pp. 148-157, figs. 6).—An illustrated study of the germinating coconut.

The grafting of coffee, W. M. VAN HELTEN (Meded. Cultuurtuin [Buitenzorg], No. 4 (1915), pp. 11, pls. 3, figs. 3).—Methods of grafting coffee are described, and a list is given of the grafts of various varieties of imported coffees in the Buitenzorg gardens in 1914–15.

Growing melons on trees, J. E. HIGGINS (Jour. Heredity, 7 (1916), No. 5, pp. 208-220. figs. 7).—An account of the papaya with special reference to irregularities in sex and methods of breeding desirable types. The subject matter is based largely on the work of the author and V. S. Holt at the Hawaii Experiment Station (E. S. R., 30, p. 841).

Top-working pecan trees, E. J. Kyle (Agr. and Mech. Col. Tex. Ext. Bul. B-21 (1916), pp. 7, figs. 6).—Directions are given for top-working pecan trees by using different methods of budding.

Commercial production of thymol from horsemint (Monarda punctata), S. C. Hood (U. S. Dept. Agr. Bul. 372 (1916), pp. 12).—As a result of selection experiments with horsemint (M. punctata), here briefly described, the author has been successful in securing an improved form more luxuriant in growth and with a higher thymol content than in the wild form. It is believed that the selection work has been carried far enough to warrant the use of this improved form for the commercial production of thymol in the United States. Cultural methods for horsemint are here discussed, together with methods of harvesting, distillation, and extraction of the thymol.

During the past five years areas up to one acre in extent have been grown on various soils. The results show that an average production of 20 lbs. of

oil, or about 12.86 lbs. of pure thymol, per acre from first-year plantings may be regarded as a fair crop. The estimated returns based on the work done thus far show that a profit of about \$16 per acre may be expected as an average for a 5-year period. Hence, it is concluded that the production of thymol might be profitable when grown in connection with other oil-yielding plants for which a distilling apparatus is required.

Beautiful gardens in America, Louise Shelton (New York: Charles Scribner's Sons, 1915, pp. XVI+[87], pls. 135).—An illustrated work in which are shown types of American gardens, covering all sections of the country. The aim has been to show those gardens which represent the development of the owner's ideal rather than imitations of foreign types of formal gardens,

Every woman's flower garden, Mary Hampden (New York: Duffield & Co., 1915, pp. IX+353, pls. 5, figs. 83).—A popular treatise on ornamental gardening with suggestions relative to garden design and plants for different types of gardens.

Notes on new plants and plants not well known, W. Hunt (Ann. Rpt. Hort. Socs. Ont., 10 (1915), pp. 57-64, figs. 2).—This comprises a brief review of some of the newer or less-known plants that have been tested in the flower borders and grounds of the Ontario Agricultural College during the past five years. Special attention is given to those that have proved to be most adapted for the amateur's garden.

Popular hardy perennials, T. W. Sanders (London: W. H. & L. Collingridge, [1916], pp. [6]+410, pls. 17, figs. 242).—This work deals with popular hardy perennials relative to their cultivation in beds, borders, the wild and woodland garden, and by the water side. The propagation of hardy perennials is also discussed, and descriptions given of the most attractive, useful, and easily grown genera, species, and varieties.

Breeding Nephrolepis ferns, S. Boshnakian (Jour. Heredity, 7 (1916), No. 5, pp. 225-236. figs. 8).—An account of the Nephrolepis ferns with reference to the development of different types of sports and methods of propagating and disseminating them.

The history, development, and propagation of the lilac, J. Dunbar (Ann. Rpt. Hort. Socs. Ont., 10 (1915), pp. 75-81).—An address before the Horticultural Societies of Ontario, 1915, in which the author discusses the history of the lilac and the development of the present improved types. A selection is given of the most distinct varieties of lilacs.

Preliminary experiments in poppy breeding, R. RANNINGER (Ztschr. Pflanzenzücht., 4 (1916), No. 1, pp. 45-64).—The results are given of some breeding and selection experiments with poppies, conducted in 1914 and 1915.

The American rose annual, edited by J. H. McFarland (Harrisburg, Pa.: American Rose Society, 1916, pp. 153, pls. 10, figs. 7).—This is the first of a series of annuals to be published by the American Rose Society. It discusses the aims and purposes of the society and contains articles dealing with varieties, the adaptation of the rose to extended uses, rose breeding, the literature of the rose, the enemies of the rose, rose gardens in different parts of the United States, the value of local rose organizations, cut flower rose growing, and the work of the American Rose Society. A partial list is given of American hybridized roses, with parentage and date of introduction so far as ascertainable.

The best hardy conifers, E. H. WILSON (Gard. Mag. [N. Y.], 22 (1915), No. 5, pp. 145-150, figs. 18).—Descriptive notes are given on a large number of hardy conifers adapted for ornamental planting.

FORESTRY.

Forestry handbook.—I, Forest principles and practice, edited by R. Dalbymple Hay (Sydney: Govt., 1915, pp. 87, pls. 21, figs. 45).—The present part of this handbook consists of a summary of useful information bearing upon the principles and practice of forestry in New South Wales. The subject matter is presented under the following general headings: General principles of forestry, climatic and protective influence of forests, afforestation, reafforestation, identification of timbers, measurement and mensuration (weight of timber, forest assessment and survey, forest working systems, and timber physics), a treatise on timber tests, and a summary of results.

A practical treatise on silviculture, A. Jolyet (Traité Pratique de Sylviculture. Paris: J. B. Baillière & Sons, 1916, 2. ed., rev., pp. 724, figs. 130).—This work comprises a completely revised edition of Traité Pratique de Sylviculture: Les Forêts, written by L. Boppe and the author, previously noted (E. S. R., 12, p. 756). The work has also been considerably enlarged.

Silviculture, E. MARSDEN (Ann. Rpt. Bd. Sci. Advice India, 1914-15, pp. 120-123).—A brief statement of progress made in the more important silvicultural investigations during the year.

The selection strip-felling and its system, C. Wagner (Der Blendersaumschlag und sein System. Tübingen: H. Laupp'schen Buchhandlung, 1915, 2. enl. ed., pp. XII+382, pls. 2, figs. 75).—The present edition of this work (E. S. R., 27, p. 444) has been revised and slightly enlarged.

The green book (Bingham, Me.: Kennebec Valley Protec. Assoc. [1916], pp. 32, figs. 10).—A manual for the use of lumbermen, woodsmen, and sportsmen containing the laws of the State of Maine relating to protection of the forests from fire and miscellaneous information of value in the woods.

Railroad fire prevention, W. T. Cox (Minn. Forest Serv. Bul. 2 (1914), pp. 29, figs. 18).—This report takes up the different sections of the Minnesota forest laws relating to railroads and reviews the progress made in fire prevention under each section of the laws.

The torrents of Savoie, P. Mougin (Les Torrents de la Savoie. Grenoble: Soc. Hist. Nat. Savoie, 1914, pp. XI+1251, pls. 69).—In part 1 of this work the author discusses in detail the origin of the torrents in Savoie, consideration being given to the topography of the country, geology of the soil, climate, deforestation, and torrential legislation. Part 2 consists of monographs on the principal torrents of Savoie.

The importance of private forestry in Japan, O. Shishido (Jour. Col. Agr. Tohoku Imp. Univ., 7 (1916), No. 1, pp. 99).—This paper gives an account of the past and present development of private forestry in Japan, discusses the economic importance both to the individual and to the State of the development of private forests, and suggests methods leading to the better development and utilization of these forests.

Extracts from the bulletin of the Forest Experiment Station, Meguro, Tokyo (Tokyo, Japan: Bur. of Forestry, Dept. Agr. and Com., 1915, pp. II+221, pls. 34, figs. 4).—The extracts here listed are from the bulletin of the Forest Experiment Station, Meguro, Tokyo, and are based on investigations made during the period from 1905 to 1914:

Investigation of Tree Seeds in Relation to the Producing Districts of the Mother Trees and Their Descent, by H. Shirasawa (pp. 1-14); Experiments on the Preservation of Principal Forest Tree Seeds, by H. Shirasawa and M. Koyama (pp. 15-27); Composition of Fallen Leaves of Forest Trees and Their Quantities (pp. 28-33), and The Proper Season for Application of Fertilizers

to Sugi (Cryptomeria japonica) and Hinoki (Chamacyparis obtusa) Seedlings and the Efficacy of Fertilizers (pp. 36-41), by S. Moriya; Investigation of the Transverse Strength in Wood (pp. 42-54), and Determination of the Calorific Power of Wood (pp. 55-58), by K. Moroto; Experiment of the Electric Resistance in Wood, by J. Hiruma (pp. 59-65); Charcoal Burning in Japan (pp. 66-76), and Condensation of Wood Vinegar in Charcoal Burning in Japan (pp. 77-80); by S. Mimura; Tapping of Lac, by M. Moriya and H. Shirasawa (pp. 95-108); Notes on "Shiitake" (Cortinellus shiitake) Culture (pp. 109-114), Researches on the Culture of "Matsudake" (C. edodes) (pp. 115-122), and Researches on the "White Judas' Ear" (Tremella fuciformis) (pp. 123-126), by S. Mimura; Notes on the Analytical Interpretation of Growth Curves for Single Tree and Stands and on Application for the Construction of Yield Table for Sugi (C. japonica) (pp. 151-202), and Investigation on Form Height Tables for the Principal Conifers and Some Broad-Leaved Trees in Japan and Bases on Which They May Be Constructed (pp. 203-221), by W. Terazaki.

An inventory of Florida's forests and the outlook for the future, R. M. HABPER (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 2, pp. 5-24, figs. 12).—A survey of the forests of Florida with reference to the area and density of the forests, their distribution and character, frequency of fire in different types, composition, prevalence of species, rate of growth and composition, and the influence of fire and agriculture on the permanence of forests.

Biennial report of the forestry commission for the years 1913-14, W. R. Brown, J. E. Tolles, and B. F. Greek (Bien. Rpt. Forestry Com. N. H., 1913-14, pp. 114, pls. 14).—A progress report of operations conducted by the forestry commission, principally along the lines of forest fire protection, reforesting waste and cut-over land, acquisition and management of state forest lands, and educational work among woodland owners.

Report of the director of forestry for the year 1915, R. H. CAMPBELL ET AL. (Dept. Int. Canada, Rpt. Dir. Forestry, 1915, pp. 102, figs. 23).—The report includes a review of the several lines of work carried on during the year, and detailed reports of the work of the tree planting division and on the forest reserves in the separate Provinces, together with the report of the Forest Products Laboratories of Canada.

Forest products of Canada, 1914.—Lumber, lath, and shingles, compiled by R. G. Lewis and W. G. H. Boyce (Dept. Int. Canada, Forestry Branch Bul. 56 (1916), pp. 62, pl. 1).—A statistical report on the production of lumber, lath, and shingles in the various Provinces of Canada during 1914, including information relative to the quantities of each species of wood used.

Economic forest products, C. E. C. Cox (Ann. Rpt. Bd. Sci. Advice India, 1914-15, pp. 124-132).—A progress report for the year 1914-15 relative to investigations dealing with forest products.

DISEASES OF PLANTS.

Wound parasitism and predisposition, F. Heske (Centbl. Gesam. Forstw., 40 (1914), No. 11-12, pp. 456-461).—This is a discussion of the relations of host, parasite, enzym, etc., concluding with the statement that wound parasitism requires a real predisposition of the host plant to attack, consisting in an alteration of the natural state of the host as a primary or contributory condition. The situation as regards the plant may also be such as to render attack comparatively easy but yet not inevitable. This predisposition consists not only in the susceptibility of the plant, but may relate to influences acting upon the infective bodies also.

Report of the department of vegetable pathology and entomology, P. Cardin (Estac. Expt. Agron. [Cuba], Informe An., 3 (1909–1914), pp. 98–173, pls. 5).—This report, covering the period from July, 1909, to July, 1914, contains an account of insect pests and fungus parasites, the host plants being arranged in alphabetical order according to their native names in Spanish, with references to bulletins, circulars, etc., in cases in which they have been noted previously.

Smuts of grain and forage crops in Kansas, L. E. MELCHERS (Kansas Sta. Bul. 210 (1916), pp. 3-38. figs. 20).—After giving general statements regarding the amount of loss due to smuts, the author describes the important smut diseases in Kansas, grouping them under the headings of corn smut and head smut of the sorghums; kernel smut of the sorghums, stinking smut of wheat, smut of oats, covered smut of barley, and smut of millet; and the loose smuts of wheat and barley. These different cereal diseases are described at some length and suggestions given for their control.

In connection with the control of loose smut, the author urges the necessity for seed plats so isolated as to prevent infection.

Experiments on varietal resistance to the bean and cotton anthracnose diseases, C. W. Edgerton and C. C. Moreland (Louisiana Stas. Bul. 155 (1916), pp. 24, figs. 4).—A report is given of some experiments on the varietal resistance of beans and cotton to anthracnose diseases.

The experiments with beans were carried on in both the field and the green-house in 1914, in 1915 in the field, and in the winter of 1914–15 in the green-house, cultures of Colletotrichum lindemuthianum from different sections and from different varieties of beans being tested. As a result of their experiments the authors conclude that the bean anthracnose fungus is composed of different strains which affect different varieties of beans differently. Some varieties were susceptible to many different strains of the fungus, while others were resistant to some strains but susceptible to others. Some varieties of beans were found practically immune to some strains of the fungus. The reason for this behavior is attributed to the fact that the bean anthracnose fungus is not variable, and is unable to adjust itself to slight variations in the host plant, and as varieties of beans are said not to cross readily there are no intermediate forms, which would permit the specialization seen in the different strains.

The experiments with cotton anthracnose (*C. gossypii*) were conducted in the field, as it was impossible to grow a sufficient amount of cotton to maturity in the greenhouse. The data secured were obtained by natural infections in which the varieties were grown between rows of badly infected plants, and by artificial infections in which the flowers were inoculated with pure cultures of the anthracnose fungus. In the case of the experiments with cotton, the anthracnose fungus was found more variable and was able to adjust itself to variations in the host plant more readily than the bean anthracnose fungus. Cotton varieties were not found to show any marked variability in regard to their resistance to anthracnose. All the varieties tested seemed very susceptible to the disease, and, although in some cases slight differences were noted, these are not considered of importance.

A rust of Astragalus sinicus and two fungus diseases of mulberry, H. Nomura (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 9 (1911), pp. 37, 38).—Descriptions are given of the supposedly new species of fungi, Coryneum mori and Phoma niphonia on Morus alba, and Tuberculina nomuriana on A. sinicus.

A new smut fungus on Arrhenatherum elatius, H. C. Schellenberg (Ber. Deut. Bot. Gesell., 33 (1915), No. 7, pp. 316-328, pl. 1, fig. 1).—A supposedly

new smut fungus is described under the name *Ustilago arrhenatheri*, in connection with abnormalities produced thereby on the host, *A. elatius*.

Studies on the dying out of pepper vines in the Dutch East Indies.—I, Summary of previous investigations, A. A. L. RUTGERS (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 18 (1915), pp. 28).—A general survey is given of pepper culture in the Dutch East Indies, more particularly of pepper diseases of economic importance, with special mention of results reported by some investigators in this and neighboring regions. Mention is made of a wilt disease associated with the presence of a fungus in the wood vessels. In some regions nematodes have been found in the roots of the plant. The connection between the above mentioned parasites and the losses associated therewith has not yet been determined. Results obtained from studies at the government farm at Taliperamba (Madras) emphasize the importance of the method of manuring and cultivating in connection with the premature dying of pepper vines.

Bacterial rot of stored potato tubers, C. M. Hutchinson and N. V. Joshi (Mem. Dept. Agr. India, Bact. Ser., 1 (1915), No. 5, pp. 113-135, pls. 5).—It is stated that four species of bacteria are found to be concerned in the rotting of potato tubers in India. One of these, numbered but not named, is invariably present in the rotting tubers examined. Infection takes place from without, differing in this respect from that due to Bacillus solanacearum. Preventive measures include the avoidance of mechanical injury in handling, storing in dry, coarse sand after immersion in 2 per cent copper sulphate solution with subsequent drying and periodical inspection to prevent infection of sound tubers.

A pathological and physiological study of the black heart of potato tubers, E. T. Bartholomew (*Centbl. Bakt. [etc.], 2. Abt., 43 (1915), No. 19-24, pp. 609-639, pls. 3*).—The author's preliminary studies (E. S. R., 30, p. 149) have been followed up by further studies of the injury and its causation,

It is stated that black heart of potato is produced, not by a parasitic organism but by abnormal physiological changes. It may be produced artificially by subjecting the tubers to a temperature of from 38 to 48° C. (100.4 to 118.4° F.), the optimum being 42 to 44°, and the optimum period of time being 15 to 20 hours. All of the 16 varieties experimented with proved to be susceptible to this trouble, which may be prevented by supplying sufficient oxygen during the period of heating, for which purpose a constant stream of air is not sufficient. The tissues do not blacken if the potatoes are kept in an atmosphere devoid of oxygen after removal from the oven. Affected tubers, if not cut open, form after seven to ten days an increasing hollow in the center due to the shrinkage of the tissue. This can not be detected from an outside view. The colors produced, which range from light pink to coal black, are thought to be due to the presence of an oxidizing enzym, tyrosinase, and a chromogen, tyrosin, which interact in the presence of free oxygen and are found in both normal and abnormal tissues of the potato tubers. The amino acid content increases greatly during the period of heating. The discoloration is said to be due to the presence of a substance known as melanin or humin.

The formation of black heart may be prevented by proper ventilation and the maintenance of a temperature not above 35°.

Late potato blight in Iowa, A. T. Erwin (Iowa Sta. Bul. 163 (1916), pp. 286-306, figs. 8).—The result is given of an investigation of the late blight of potato, particularly with reference to the influence of moisture supply, humidity, and temperature. Three pronounced outbreaks of the late blight are reported to have occurred in Iowa during the past 45 years. These were in 1885, 1903, and 1915.

In studying the meteorological conditions in connection with outbreaks of this disease, the author claims that the climatic conditions in Iowa are generally unfavorable to such outbreaks, but that they sometimes cause serious loss. The climatic conditions under which late blight occurs in Iowa are a high degree of humidity with heavy dews and midsummer temperatures lower than usual. An excess of rainfall and a predominance of cloudy weather are predisposing factors.

Some notes are given on disease-resistant varieties, the spread of the disease through seed infection, storage qualities of infected potatoes, and the effect of time of planting on the degree of injury. Diseased potatoes, it is claimed, may be held in storage at a very slight loss from dry rot if the temperature is sufficiently low and the potatoes are taken out of storage only a short time before they are used. Early planting and the use of Bordeaux mixture are considered effective measures for preventing late blight in Iowa.

Straight head in rice, F. C. Quereau (Louisiana Stas. Rpt. 1915, p. 31).—
The author gives a brief account of a disease or condition in rice which seems to occur on soils containing an abundance of vegetable matter. It is not definitely known whether the disease is due to physical conditions or to some specific organism. The only preventive treatment at present known is to delay the initial irrigation as long as possible, or, if necessary to irrigate because of weeds or grass, to drain the land about 15 days after the first flooding, allowing it to become perfectly dry. In a number of cases, this treatment is said to have prevented the condition designated as straight head.

A disease of sugar beets, P. Berthault (Jour. Agr. Prat., n. ser., 28 (1915), No. 56, pp. 550, 551, figs. 2).—It is stated that in the region around Paris and northward, industries dependent upon the sugar-beet crop have been considerably affected of late by the development of unusual virulence in the attacks of Cercospora beticola, which has previously appeared in this district but generally in mild form. Changes in coloration and inferior growth are associated with injuries to the leaf tissue.

Cercospora beticola attacking sugar beets, E. SAILLARD (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 1, pp. 47-49).—The author discusses the unusual attacks by C. beticola on sugar beets in 1915 and the effects thereof on beet products, some of which were considerably altered in their proportions, as shown by comparative tables for 1915 and some earlier years.

A disease of sugar beets, A. Morvillez (Jour. Fabric. Sucr., 56 (1915), No. 11, pp. 1, 2).—The author considers the losses to the sugar-beet industry in 1915 as due primarily and largely to insufficient nutrition.

Sugar beet disease, P. BERTHAULT (Jour. Agr. Prat., n. ser., 29 (1916), No. 2, pp. 35, 36).—The author, discussing the above contributions by himself, Saillard, and Morvillez, considers the attack by Cercospora beticola and the associated abnormal chlorosis as closely related phenomena, the latter being probably dependent upon the former.

Internal action of chemicals on resistance of tomatoes to leaf diseases, J. B. S. Norton (Maryland Sta. Bul. 192 (1916), pp. 17-30, fig. 1).—After reviewing the literature describing the effect of soil applications, direct injection, and the use of serums and toxins for the prevention of plant diseases, the author describes some experiments carried on in 1912 and 1913, in which about 50 chemicals were employed to determine their effect on infection of tomatoes by Septoria lycopersici and Cladosporium fulvum.

The plants were grown in paraffin-covered paper pots suspended in glass tumblers above solutions of different proportions of the various chemicals, their roots extending downward to the solution of the chemical, which did not come in contact with the soil.

In a few instances, there was some indication that concentrations lower than those causing injury might reduce the development of the leaf parasites to some extent. This was true of potassium nitrate, sodium acetate, morphine sulphate, calcium nitrate, copper sulphate, lime water, sodium tungstate, and potassium permanganate. In some cases there was less leaf disease developed, particularly in case of *S. lycopersici*, on the higher concentrations where these were not strong enough to cause injury, but in general the results were negative.

Some orchard diseases and their treatment, C. R. Obton (Proc. State Hort. Assoc. Penn., 55 (1914), pp. 43-56, pls. 6).—The author discusses some of the more destructive orchard diseases prevalent in Pennsylvania, the number of which has greatly increased during recent years, naming their several orchard and wild hosts, describing their symptoms, and pointing out various control measures. Those taken up are fire blight (Bacillus amylovorus), bitter rot (Glomerella rufomaculans), black rot (Sphæropsis malorum), apple rust (Gymnosporangium juniperi-virginianæ), orange rust of quince (G. germinale), and brown rot of peach, plum, and cherry (Sclerotinia cinerea), with mention of others of less importance.

Experiments with rust and Coryneum of fruit trees, A. Cadobet and A. Desmoulins (Prog. Agr. et Vit. (Ed. VEst-Centre), 36 (1915), No. 46, pp. 468-471).—Discussing the characters, importance, and extension of these two diseases, also tests with remedial measures made or reported, the authors conclude that the higher concentrations of the sprays sometimes used are unnecessary, 2 per cent being considered as sufficient for Bordeaux mixture or neutral copper acetate. The materials added to the sprays to increase their capacity for spreading and adhesiveness do not appear to have been very successful except in case of gelatin added to copper acetate. Lime sulphur sprays are said to have been very inferior in their results to the preparations based on copper.

The development of perithecia in Venturia inæqualis, K. KILIAN (Ber. Deut. Bot. Gesell., 33 (1915), No. 4, pp. 164-168, figs. 2).—The author gives an account of his observations, so far as completed, on the developmental history, in relation to apple leaves, of Fusicladium dendriticum (the conidial stage of V. inæqualis) associated with apple and pear scab.

Influences affecting cherry culture, Sprenger (Cultura, 27 (1915), No. 325, pp. 291-295).—Among the conditions mentioned as influencing returns from cherry culture in southerly portions of the Netherlands are various biological, physiological, and weather conditions, and pathological fungi, including Monilia, Coryneum, Valsa leucostoma, and Armillaria mellea.

Common diseases of the grape, M. T. Cook (New Jersey Stas. Circ. 55 (1916), pp. 3-8, figs. 2).—Descriptions are given of some of the more common diseases of the grape and suggestions offered for their control.

A brief report is also presented of grape-spraying experiments in 1915, in which an early spraying was given certain plats, and the results contrasted with those from plats sprayed as in the general practice in that vicinity. The plats receiving the extra spraying were given six applications, the first early in May, while the others received five applications, beginning June 17. At harvest, rows were selected for measurement from the different plats, and those which had received the extra spraying in May yielded an average of 66.5 baskets, or 25 baskets per four rows more than those treated in the ordinary manner.

A vine disease due to a Hypochnus, A. Lendner (Bul. Soc. Bot. Genève, 2. ser., 6 (1914), No. 4, pp. 104-106, fig. 1).—A fungus described as H. burnati n. sp. is considered as secondarily parasitic or saprophytic on grapevines. It may be related to the lime content in the soil.

[Reports on grape downy mildew] (Rev. Vit., 43 (1915), Nos. 1096, pp. 17, 18; 1097, pp. 31–33; 1098, pp. 48, 49; 1099, pp. 64–69; 1100, pp. 73–88; 1101, pp. 93–107; 1102, pp. 113–120; 1103, pp. 133–143; 1104, pp. 153–168; 1105, pp. 173–184; 1106, pp. 206–209; 1107, p. 229; 1108, pp. 233–242; 1109, pp. 253–260; 1110, pp. 278–285; 1111, pp. 296–301; 1112, pp. 316–322; 1113, pp. 336–338; 1114, pp. 350–356; 1116, pp. 388–392; 1117, p. 410; 1119, pp. 447–450; 1120, p. 465).— This series of articles is made up of information and suggestions received during the latter part of 1915 from correspondents at numerous points in France and some in neighboring countries regarding the appearances, phenomena, and effects of grape downy mildew, and regarding such related or unrelated factors as insects, black rot, weather conditions, and susceptibility, with some discussion of experiences and observations during previous years.

Downy mildew in Aude, F. Cazenave (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 36 (1915), No. 34, pp. 188–190).—The author reports that 10 sprayings with Burgundy mixture containing 2 per cent copper sulphate applied during the period from May 12 to August 12 gave adequate protection against downy mildew.

Downy mildew on direct-bearing grapevines, S. Obiedoff, J. Baquero, and D. V. Pehlivanoglou (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 36 (1915), Nos. 30, pp. 82-88; 31, p. 117, figs. 2).—This is a report on the phases and degrees of recent attack by grape downy mildew on direct bearers which have been considered as nearly or quite immune to such attack. Only a very limited number, however, are said to have proved resistant.

Causes of success or failure of grape downy mildew, L. RAVAZ (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 36 (1915), No. 32, pp. 125-130).—The author discusses the employment of different concentrations and frequencies in the sprays used against grape downy mildew, and the probability of the development of a strain of this fungus more than ordinarily resistant to fungicides.

Treatment for downy mildew in rainy years, G. Héron (*Prog. Agr. et Vit.* (*Ed. UEst-Centre*), 36 (1915), No. 34, pp. 185–188).—The author's observations are said to indicate that in years of heavy rainfall a solution of 2 to 3 per cent copper content is preferable to the usual strengths used in copper sprays. Of these sprays Burgundy mixture is preferred, especially in the acid form, which is said to maintain on leaves and fruits a certain amount of soluble copper. It is thought prudent to apply after heavy rains a simple treatment consisting of a 0.4 or 0.5 per cent solution of copper sulphate. It is suggested that cupric powders may also be profitably employed.

Copper fungicidal powders, H. Fonzes-Diacon (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 36 (1915), No. 28, pp. 37-41).—It is claimed that acid powders contain copper soluble in water, which is capable of exercising immediate fungicidal action upon mildew spores, and also copper soluble in water containing carbon dioxid, which is also capable of acting upon the spores, but more slowly. Too high acidity may scorch both leaves and fruits. Neutral powders contain copper more or less readily soluble in rain water charged with carbon dioxid, giving a slower fungicidal effect. The alkaline powders do not seem to be effective in this regard.

The influence of temperature on decomposition in Bordeaux mixture, O. Butler (Prog. Agr. et Vit. (Ed. l'Est-Centre), 36 (1915), No. 27, pp. 15-18, pl. 1).—A discussion is given of differences in the properties and effects of Bordeaux mixture corresponding to variations in the composition, temperature during preparation, and age of the mixture.

Treatment of grapevines with hot water and hot sprays, L. Semichon (*Rev. Vit.*, 43 (1915), No. 1096, pp. 9-12).—This is mainly a reply by the author to some criticisms of the claims regarding the real temperatures of hot water

when used as fungicide or insecticide as previously discussed (E. S. R., 32, p. 447; 34, pp. 50, 243).

Treatment of vines and vegetation with hot water, L. Semichon (*Rev. Vit.*, 43 (1915), *No. 1118*, pp. 413. 414, fig. 1).—Results are presented in numerical and graphical form of the relation found to exist between the distance from the nozzle and the lowering of the temperature in case of sprays applied with nozzles of different kinds and sizes.

Theory of temperature change in hot sprays, A. Chauvigné (Rev. Vit., 43 (1915), No. 1118, pp. 415-417, fig. 1).—This article reports a study along lines similar to the above. It is stated that the lowering of the temperature is not constant throughout the length of the jet, the maximum rate of temperature decrease being attained at 20 cm. (7.8 in.) from the orifice of the nozzle in the experiments reported.

Theory and practice in regard to the cooling of hot sprays, L. Semichon (*Rev. Vit.*, 43 (1915), *No.* 1118, pp. 417-419).—This is a discussion of the above notes, including supposedly variable unknown factors.

Brusca of olive, G. Pollacci (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 9 (1911), pp. 26-28).—Two fungi described as new species on olive leaves are named Coniothyrium olew and Septoria olew.

Cacao and its local diseases, T. G. Ghofulpo (Philippine Agr. and Forester, 4 (1915), No. 8, pp. 162-172).—Giving the results of a study of cacao culture in the Philippines, particularly in the region around the College of Agriculture, the author discusses various cacao pests and diseases. The fungi which are found to be very commonly injurious are the Diplodia or Lasiodiplodia form of Thyridaria tarda, Phytophthora omnivora, Nectria theobroma, and N. bainii.

Bordeaux mixture, if applied thoroughly and in time, is said to be very satisfactory for both fungus pests and insect enemies of cacao. Necessary or helpful conditions for successful cacao culture are general sanitation, seed selection, spacing, fertilization of the soil, early pruning, and destruction of affected parts.

Coconut bud rot, J. B. RORER (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 4, pp. 129, 130).—In a summary of a report on the work done to date in connection with bud rot, it is stated that experiments at Roxborough, Tobago, and Toco, Trinidad, indicate that frequent spraying with Bordeaux mixture can be relied upon to prevent serious attack by this disease if the crowns of the trees are not over 15 to 18 ft. from the ground. The infected portions are chiefly the bases of the leaves, the flower stalks, the spathes, and the whole of the soft upper portion of the stem.

The claim that *Bacillus coli* is the cause of bud rot is said to be undergoing tests.

A study of native coffee production, F. D. Luistro (*Philippine Agr. and Forester*, 4 (1915), No. 8, pp. 153-161).—This is a discussion of coffee culture in the Philippines, including the decrease during recent years in the output with its causes and their possible remedies, as manuring, pruning, and more particularly, spraying.

It is stated that experiments carried out in the Lipa and the Los Baños districts, where *Hemileia vastatrix* is said to be the most destructive coffee disease, show that a considerable saving was effected by the use of Bordeaux mixture. Pruning is said to lessen the degree of infection.

A brief bibliography is appended.

A coffee disease in Mexico, R. Farnett (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 9 (1911), pp. 36, 37).—A disease of coffee in Cuicatlan, in the Mexican State of Oaxaca, is ascribed to a fungus described as Cercospora herrerana n. sp., which is contrasted with C. coffeicola.

A new Cylindrosporium, M. Turconi (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 9 (1911), pp. 28-30).—C. pollacci n. sp. is the name given to a fungus parasitic on Ilex furcata.

The hydropsy of Madake (Phyllostachys bambusoides), S. Kawamura (Extracts from Bul. Forest Expt. Sta., Tokyo, 1915, pp. 127-130, figs. 4).— Madake has recently been increasingly affected with a disease characterized by accumulations of water in the stem, especially the middle portions, but not in the uppermost internodes. The leaves gradually fall and the stem becomes weak and unfit for use. The symptoms and their alterations are described in some detail. The cause of the trouble has not been determined.

The red plague of Sugi (Cryptomeria japonica) seedlings, S. KAWAMURA (Extracts from Bul. Forest Expt. Sta., Tokyo, 1915, pp. 131-133, fig. 1).—It is stated that since the red plague of Sugi became known a few years ago in Japan, the trouble has spread until it has now been reported from various parts of the country. The symptoms of the disease are described.

The author's investigations since 1911 have led to the conclusion that the disease attacks only this plant and is confined to seedlings under five years of age. Of the three fungi noted in this connection, Pestalozzia appears to be usually associated with other fungi, mostly on old, decayed leaves, and Cercospora is still under investigation, so that this report is confined chiefly to a discussion of Phyllosticta. The fungus attacks first the lower and then the higher leaves, causing discoloration, and later the twigs, causing dark brown spots on the surface, and eventually killing the leaves, causing complete failure of growth.

A disease of immortel trees, J. B. Rober (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 4, pp. 128, 129).—A disease affecting Erythrina velutina is described, in which the leaves show first a pale green, then a yellow color. This is followed by a dieback, the branches falling away gradually and the bare, dead trunk finally rotting and falling to the ground. This occurs in widely separated groups of from 10 to 20 or more trees. Often, though not always, the cacao trees under the dying immortel trees are affected in much the same manner. The trouble may be connected with insufficient drainage. No parasites have yet been shown to produce the disease, and the symptoms suggest root trouble, poor soil conditions, or bad water relations. Deep and thorough drainage appears to be the best means of control.

Hypoderma deformans, an undescribed needle fungus of the western yellow pine, J. R. Weir (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 8, pp. 277-288, pl. 1, figs. 4).—A technical description is given of H. deformans n. sp., which is said to cause a serious needle disease of the western yellow pine (Pinus ponderosa) in parts of Idaho, Washington, and Montana.

The fungus is said to be a true parasite, attacking the foliage of all age classes. The first sign of infection is usually a slight browning of the tips of the needles, or, in regions of heavy infection, the entire needle may assume a straw yellow color deepening to a brown on the first appearance of the apothecia. The terminal shoots do not attain their normal development, and witches' brooms are frequently produced.

The author considers this fungus a possible cause of disease in nurseries, although, up to the present time, it has not been found in the forest tree nursery. Cutting out and burning the infected parts or trees are recommended as means of control.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

Animal guide; North American wild animals, C. K. REED (Worcester, Mass.: Author, 1915, pp. 253, figs. 60).—This small pocket guide includes descrip-

tions of 60 North American wild animals illustrated in color from original paintings by H. F. Harvey.

A list of British birds compiled by a committee of the British Ornithologists' Union (London: British Ornithologists' Union, 1915, 2. rev. ed., pp. XXII+430).—This is the second revised edition of the British Ornithologists' Union list, the first of which was published in 1883. Under each species are given the common name, synonymy, distribution in the British Isles, and general distribution. The appendixes include a list of species which have been recorded as having been found in the British Islands, but on evidence which the committee do not regard as entirely satisfactory; a list of names which in the opinion of the committee should be retained, together with the corresponding names under the Rules of Nomenclature as drawn up by the International Congress of Zoology at their successive meetings; and a discussion of the reasons for the change of old names or for the nonadoption of changes which have been advocated by recent authors, together with the method of fixation of the types of the various genera used in the list.

Birds of the Indian hills, D. Dewar (London and New York: John Lane, 1915, pp. 264).—The several parts of this popular work deal with the birds of the Himalayas, the common birds of the Nilgiris, and the common birds of the Palni Hills. The vernacular names of Himalayan birds and of Nilgiri birds are given in appendixes and a subject index is included.

The entomological and ornithological collector's handbook, J. SINCLAIR (Los Angeles, Cal.: Author, 1915, pp. 80).—A handbook of information for collectors.

Agricultural entomology, H. Osborn (*Philadelphia: Lea and Febiger, 1916, pp. IV+17-347, pl. 1, figs. 252).*—This work has been prepared for the use of students, farmers, fruit growers, and gardeners.

Insect pests of Lima beans in St. Vincent, S. C. Harland (Agr. News [Barbados], 14 (1915), Nos. 352, pp. 346, 347; 353, p. 363).—An undetermined Cryptorhynchus borer; the bean leaf roller (Eudamus proteus), held in check by parasites; an undetermined leaf blotch miner; and the larvæ of an undetermined moth are said to be the most important enemies of Lima beans in St. Vincent.

Insect pests of the orchards and gardens of Idaho and their control, W. C. EDMUNDSON (*Idaho Sta. Bul. 87* (1916), pp. 30, figs. 12).—A popular descriptive account with control measures.

The insects injurious to fruit trees, P. Lesne (Jour. Agr. Prat., n. ser., 28 (1915), Nos. 41, pp. 312-314, pl. 1; 42, pp. 327, 328; 53, pp. 503-506, pl. 1; 56, pp. 555, 556).—A general account of insects attacking fruit trees, accompanied by colored plates of the more important forms.

[Citrus insects in the Isle of Pines], F. S. EARLE and J. M. ROGERS (San Pedro [Isle of Pines] Citrus Path. Lab. Ann. Rpt., 1 (1915), pp. 11-21, figs. 2).—An account of the more important citrus insects and means for their control.

The locust borer (Cyllene robiniæ) and other insect enemies of the black locust, H. Garman (Bien. Rpt. State Forester Ky., 2 (1915), pp. 32-63, pls. 21).—The locust borer, an extended account of which by Hopkins has been previously noted (E. S. R., 18, p. 159), is said to occur throughout Kentucky, its numbers being in proportion to the abundance of locust trees. Biological observations of this beetle and its natural enemies are reported.

It is pointed out that since the adults are dependent on goldenrod pollen and are abundant only where it may be secured, the destruction of goldenrod in the vicinity of plantings or the spraying thereof with arsenate of lead about the middle of September are valuable means of lessening the injury. As a

further precaution the spraying of the trunks of trees with lead arsenate about the first of September when the beetles begin to emerge from the trees is suggested and the destruction of old badly-infested locust trees in the vicinity of plantings is recommended.

The other insects mentioned as infesting the wood of the trees include the carpenter moth (*Prionoxystus robiniw*), the twig miner (*Ecdytolopha insiticiana*), and *Agrilus egenus*. Several insects mentioned as attacking the young twigs and leaves include the leaf miners, *Chalepus dorsalis*, *C. nervosa*, *Gracilaria lespedezæfolicila*, *Lithocolletes ostensackenella*, and *L. robiniella*; the locust leaf skeletonizer (*Gelechia pseudacaciella*); and the locust skipper (*Eudamus tityrus*). Under the heading of puncturing insects several tree-hoppers, etc., are mentioned.

Twenty-eighth report of the state entomologist on the noxious and beneficial insects of the State of Illinois, S. A. Forbes (Rpt. State Ent. Ill., 28 (1915), pp. IX+106, pls. 4, figs. 24).—This report consists of the following papers: Recent Illinois Work on the Corn Root Aphis and the Control of Its Injuries (pp. 1-62) (E. S. R., 33, p. 60), Observations and Experiments on the San José Scale (pp. 63-79) (E. S. R., 33, p. 452), and Life History and Habits of the Northern Corn Rootworm (Diabrotica longicornis) (pp. 80-86) by S. A. Forbes; and the San José Scale (Aspidiotus perniciosus), by P. A. Glenn (pp. 87-106) (E. S. R., 34, p. 162). The paper on the northern corn rootworm is based upon miscellaneous observations and operations of several years.

Forty-fifth annual report of the Entomological Society of Ontario, 1914 (Ann. Rpt. Ent. Soc. Ontario, 45 (1914), pp. 152, figs. 27).—This annual report consists of Reports on Insects of the Year, by A. Gibson (pp. 13-28); Applied Entomology in Canada: Its Rise and Progress, by C. G. Hewitt (pp. 29-41); Insects of the Season in Ontario, by L. Caesar (pp. 42-49); The Habits of Spiders, by J. H. Comstock (pp. 49, 50); Brief Notes on Some of the Injurious Insects of Quebec, 1914, by W. Lochhead (pp. 59-61); Insects Injurious in Southern Quebec, 1914, by C. E. Petch (pp. 70, 71); The 1914 Outbreak of the Army Worm in Canada, by A. Gibson (pp. 72-75), substantially noted (E. S. R., 35, p. 56); The Army Worm in Ontario in 1914, by A. W. Baker (pp. 75-90); Experiments with Poisoned Bran Baits for Locust Control in Eastern Canada, by A. Gibson (pp. 97-102), substantially noted (E. S. R., 35, p. 56); An Imported Red Spider Attacking Fruit Trees, by L. Caesar (pp. 102-107) (E. S. R., 33, p. 659); Cherry Fruit Flies, by L. Caesar (pp. 107-112), substantially noted (E. S. R., 33, p. 561); The Control of Forest and Shade Tree Insects of the Farm, by J. M. Swaine (pp. 112-116); etc.

The theory of wetting, and the determination of the wetting power of dipping and spraying fluids containing a soap basis, W. F. Cooper and W. H. Nuttall (Jour. Agr. Sci. [England], 7 (1915), No. 2, pp. 219-239, figs. 3).—An extended discussion of the subject, including a review of the literature and a list of 20 references.

Common spray materials and other insecticides, J. G. Sanders (Wis. Dept. Agr. Bul. 3 (1916), pp. 22, figs. 9).—This is a popular treatise.

Locusts or grasshoppers, F. W. URICH (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 4, pp. 120-128, pl. 1).—Brief notes are given on the occurrence of locusts in Trinidad and methods of combating them, together with an account of locust destruction in South Africa.

Combating locusts, Trabut (Bul. Agr. Algérie, Tunisie, Maroc, 21 (1915), No. 3, pp. 53-74, figs. 16).—A discussion of the methods of combating migratory locusts and of their natural enemies.

Thrips oryzæ n. sp., injurious to rice in India, C. B. Williams (Bul. Ent. Research, 6 (1916), No. 4, pp. 353-355, fig. 1).—This species is reported to be injurious to young rice.

What cacao thrips signify in Grenada, H. A. Ballou (Agr. News [Barbados], 14 (1915), No. 350, pp. 314, 315).—The cacao thrips (Heliothrips rubrocinctus) probably occurs in all parts of Grenada, where it was first found in 1898, and may occur in every cacao field. Attacks occur year after year on the same areas, on the same trees even, sometimes spreading a little, but a thrips area one year is liable or certain to be a thrips area every year, although it may never increase in numbers sufficiently to attract attention or cause any injury.

It is suggested that the cacao thrips should be considered a useful insect since it may indicate that the trees are suffering from untoward condition, thus serving as an indicator. When thrips areas have been examined, it has been found that root disease was present, the drainage was insufficient, the soil was shallow with terrace or heavy clay beneath, or there was evidently a lack of humus in the soil.

A new thrips damaging coffee in British East Africa, C. B. WILLIAMS (Bul. Ent. Research, 6 (1915), No. 3, pp. 269-272, fig. 1).—Diarthrothrips coffee n. g. and n. sp. is said to have caused serious damage to the leaves of coffee in several districts of British East Africa.

Egg and manner of oviposition of Lyctus planicollis, T. E. SNYDER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 7, pp. 273-276, pls. 4).—Species of the genus Lyctus are said to be by far the most important of the various beetles which cause the so-called "powder-post" injury to seasoned wood products so widely distributed over the world. The observations of L. planicollis here described were made at Washington, D. C., and Falls Church, Va.

The winter is passed in the larval stage, general pupation occurring about the first of April; the pupal cell is excavated near the surface of the wood, and to this cell the larvæ retreat after cutting a transverse burrow nearly to the surface for the exit of the adults. The general emergence of adults takes place during May. Oviposition began a few days after mating and was observed to take place principally during the middle of May in 1915. On May 24 many beetles were observed on radial sections of wood with their ovipositors deeply inserted into the open pores or large longitudinal vessels in the wood. The beetles seem to prefer to oviposit on those sections of seasoned sapwood where the open ends of pores are most numerous. Recently hatched larvæ were first observed on June 1, the period of incubation being 10 days at most.

It is stated that the injury by "powder-post" beetles to unfinished seasoned wood products can be prevented by simply adapting a system of inspection, classification, and methods of disposal of stock to facts in the seasonal history of the insects, as has been recommended by Hopkins (E. S. R., 24, p. 256). In the case of finished wood products it may often be practicable to treat the wood with substances to prevent attack. Judging from the facts in the seasonal history of this species, preventives should be applied before March 1.

The mealy bug of the muscat grape, F. K. Howard (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 2, pp. 67, 68, flg. 1).—The infestation of table and wine grapes in the grape-growing section of the San Joaquin Valley by the mealy bug, probably Pseudococcus bakeri, first became of economic importance in 1914. It was first found on raisin grapes in an old muscat vineyard near Armona, Kings County, Cal., in September, 1915. Up to the time of writing no satisfactory control measure had been worked out.

Phylloxera (Dept. Agr., Indus., et Com. [Vaud], Raps. Sta. Vit. et Serv. Phylloxérique, 1912, 1913, and 1914, pp. 64, each).—Reports on the reconstitution of vineyards and control work with phylloxera in the Canton of Vaud.

Notes on Samoan Coccidæ with descriptions of three new species, R. W. DOANE and G. F. Ferris (Bul. Ent. Research, 6 (1916), No. 4, pp. 399-402, figs. 3).—Notes are given on the occurrence of Coccidæ in Samoa, together with descriptions of three species new to science.

On a new coccid pest of cacao from Trinidad, E. E. GREEN (Bul. Ent. Research, 6 (1916), No. 4, pp. 377-379, figs. 3).—Philephedra theobromæ n. sp., collected on pods of Theobroma cacao in Trinidad and attended by the ant Azteca chartifex, is described as new.

On a coccid injurious to pine trees in the Himalayas, E. E. GREEN (Bul. Ent. Research, 6 (1916), No. 4, pp. 395-397, pl. 1, figs. 3).—Ripersia resinophila, which was found to occupy gummy cells of growing shoots of Pinus longifolia and P. excelsa, is described as new to science.

The soft bamboo scale (Asterolecanium bambusæ), E. O. Essig (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 2, pp. 72, 73, fig. 1).—The author records the discovery of the establishment of this pest in the United States for the first time, at Ventura, Cal., in March, 1914, and at Sierra Madre in 1915.

How to control the cottony maple scale, J. G. Sanders (Wis. Dept. Agr. Circ. 2 (1916), pp. 4, figs. 3).—A brief popular account.

Studies of comparative lepidopterology, C. OBERTHÜR (Études de Lépidoptérologie Comparée. Rennes: Author, 1913, Nos. 7, pp. 679, pls. 171; 8, pp. 88, pls. 40; 9, pt. 1, pp. 44, pls. 9; 1914, No. 9, pt. 2, pp. 180, pls. 56, figs. 6; 1915, No. 10, pp. 459, pls. 152, figs. 42).—A continuation of the work previously noted (E. S. R., 28, p. 453).

Life-histories of Indian insects.—V, Lepidoptera, C. C. Ghosh (*Mem. Dept. Agr. India, Ent. Ser.*, 5 (1914), No. 1, pp. 72, pls. 9, fig. 1).—This part (E. S. R., 31, p. 159) deals with the butterflies.

A butterfly injurious to coconut palms in British Guiana, L. D. CLEARE, Jr. (Bul. Ent. Research, 6 (1915), No. 3, pp. 273-278, pls. 3, fig. 1).—The larva of the coconut butterfly (Brassolis sophoræ) is reported to have severely attacked coconut palms in the vicinity of Georgetown during 1914. All of the green parts of the leaves were devoured, only the thick central midrib and the fine lateral veins being left. Studies of its histology, natural enemies, etc., are reported.

The possibilities of sericiculture in British colonies and dependencies, with special reference to the rearing of wild and semiwild silkworms (Bul. Imp. Inst. [So. Kensington], 13 (1915), No. 1, pp. 87-110).—An extended discussion.

The potato moth (Phthorimæa operculella [Lita solanella]).—Recent spraying experiments in Gippsland, C. French, Jr., and S. G. Harris (Jour. Dept. Agr. Victoria, 13 (1915), No. 10, pp. 614-618, figs. 2).—This pest has caused considerable loss to growers and is deemed the worst potato pest in Victoria. Due to exceptionally dry weather in Gippsland and elsewhere during the past two seasons, the moths have been exceedingly abundant and the damage caused has been very great. In some cases the whole crop has been destroyed when the plants were from 4 to 6 in. high, and in many instances the growers had to discard fully two-thirds of the tubers when bagging, owing to the depredations of the caterpillars. Experimental applications of lead arsenate to the foliage are said to have given quite beneficial results.

The grape berry worm (Polychrosis viteana), W. H. Goodwin (Ohio Sta. Bul. 293 (1916), pp. 259-307, figs. 39).—This lepidopteran, described from the United States in 1860 as P. viteana, resembles the European grape pest P. botrana anatomically, although the differences in its life history and habits

and minor anatomical differences have led to its recognition as a distinct species. It has been unusually destructive at various times in those sections of New York, Pennsylvania, and Ohio where grapes are the predominating crop, and has also been a pest in other States.

The studies of its life history and of control measures, here reported, have extended over a period of several years. The pest was found to be two-brooded, completing its life cycle twice each year. Moths transforming from the overwintering pupe emerge throughout a period of from 20 to 30 days in June and July, making the periods during which the eggs hatch of equal duration.

"Earlier publications have recommended three sprayings, one just before bloom, a second when the grapes are about as large as peas, and a third about July 10 to 15. The recent and complete life-history studies have shown that by following this program the three sprayings for berry-worm control were made before the first-brood larvæ were grown. The third spraying from July 10 to 15 was made almost a month before the eggs of the second brood of berry worms for the season were hatched, leaving small probability of sufficient poison adhering at this time to kill many of these newly-hatched worms.

"By timely, thorough spraying, in accordance with the known life-history development, the berry worms have been controlled, their injuries being reduced to an almost negligible amount. These sprayings should be extremely thorough. Arsenate of lead 4 lbs., Bordeaux 2:3:50, and 2 lbs. of dissolved soft soap should be used for the first spraying just after the blooming of the grapes, when the largest berries are about 0.125 in. in diameter. This poison spray kills many of the first-brood worms.

"The second spraying must be made just preceding the placing of the moth eggs on the grape berries and stems of the berries. In normal years the time of this spraying comes between August 3 and 12, depending upon whether the grapes bloom earlier or later than normally, or about seven weeks after the grapes bloom. This time can also be determined by placing a lot of wormy grapes in a jar about July 20 with leaves on top of the berries; tie a piece of cloth over the top of the jar and place it outdoors in the shade. Spraying for the control of the second-brood worms must be started about ten days after the first-brood worms begin to spin cocoons on the grape leaves. Use arsenate of lead paste 6 lbs., Bordeaux 2:3:50, and dissolved soft soap 2 lbs., covering every bunch with spray, applying it preferably by hand."

Life-history studies of this insect, by Johnson and Hammar, have been previously noted (E. S. R., 28, p. 453).

Ornix geminatella, the unspotted tentiform leaf miner of apple, L. Haseman (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 8, pp. 289-296, pl. 1).—This leaf miner is said to have been extremely abundant in Missouri in recent years, and has attracted the attention of fruit growers throughout the State. Its attack has largely been confined to bearing apple orchards, though considerable injury has been done to apple foliage in nurseries. Its importance is considerably lessened due to its being most abundant in the late summer and early fall.

The moth was first described and figured by Packard in 1869 as Lithocolletes geminatella and was reported by him to be abundant in New England on pear and apple. It has since been reported by entomologists as very abundant on apple in New York, as common in Connecticut, and as occurring in a number of other States.

In the present paper the author reports observations being made at the Missouri Experiment Station of its life history and habits. The egg is so small that

the author has failed to detect it on foliage. The larva always seems to break through the part of the shell which is cemented to the leaf and enters the leaf tissue at once. In the course of its development the larva molts three times, the first of which takes place on the third day and the second on the seventh or eighth day, the larva! life in the mine being about two weeks. After vacating the mine through a small hole in its floor the larva crawls about for a varying length of time before making a cocoon in which to pupate. The cocoon is almost invariably placed on the upper surface along the edge of the leaf or at its very tip. Pupation takes place soon after the cocoon is completed, the pupal period varying from a few days to a week in midsummer. In the spring the adults are abundant by the first week in May. By the middle of the month the typical tentiform mines begin to appear, and the adults of the first spring brood begin to emerge by the last of May, the life cycle being completed in from four to five weeks. The broads overlap, but beginning with May a fairly well-defined brood can be made out for each month until November. The larvæ of the October brood pupate and live through the winter on fallen leaves.

While this leaf miner is primarily a pest of the foliage of the apple, the small caterpillars have also been found developing in considerable numbers in the leaves of the crab apple and occasionally in the leaves of the haw (*Cratægus* spp.), plum, cherry, and pear. Other authors report having reared it from mines in the leaves of wild cherry.

It is pointed out that since the caterpillar enters the leaf immediately on hatching and remains in the mine until mature and ready to spin its cocoon for pupating, arsenical and contact sprays are of little value in its control. Since it passes the winter as a pupa in cocoons on fallen leaves, it can be effectively controlled by destroying the leaves early in the spring, the most practical method being to use a disk for shallow cultivation before the first of March so as to work under the leaves before the moths begin to emerge. The pest is said to be heavily parasitized. The author reared a number of parasites from it, namely, Sympicsis nigrifemora, S. tischeræ, S. metcori, Eulophus lineaticoxa, S. dolichogaster and others which have not been identified.

Cutworms, H. T. Fernald (Massachusetts Sta. Circ. 61 (1916), pp. 2).—A revision of Circular 43, previously noted (E. S. R., 32, p. 349).

Anopheles punctipennis, a host of tertian malaria, W. V. King (Amer. Jour. Trop. Diseases and Prev. Med., 3 (1916), No. 8, pp. 426-432, pl. 1).—Substantially noted from another source (E. S. R., 34, p. 358).

In a footnote the author states that it has been established that A. punctipennis is also an efficient host of the parasite of estivo-autumnal malaria, Plasmodium falciparum.

Experiments on the development of malaria parasites in three American species of Anopheles, W. V. King (Jour. Expt. Med., 23 (1916), No. 6, pp. 703-716, pls. 8).—This is a report of further experiments (see above) with the three most prevalent species of the genus occurring in the United States.

"As a result of these experiments Anopheles punctipennis is shown to be an efficient host of the organisms of tertian and estivo-autumnal malaria, A. crucians of estivo-autumnal malaria, at least, and information has been obtained upon the relative susceptibility of these two species and A. quadrimaculatus. The latter species has been known to be an efficient host since Thayer's experiments in 1900, and has been considered to be the principal species concerned in the transmission of malaria in the United States.

"With A. punctipennis, developmental forms of the exogenous or sporogenic cycle of Plasmodium vivax were demonstrated in six (85 per cent) of the

seven mosquitoes dissected, and the development of *P. falciparum*, in four (20 per cent) of twenty specimens. These four infections, however, occurred in a series of thirteen specimens fed on one person, so that the percentage was actually 33.

"With A. erucians, oocysts or sporozoites or both oocysts and sporozoites of P. falciparum were found in nine (75 per cent) of the twelve specimens dissected. No tests were made with this species and P. vivax.

"A. quadrimaculatus was employed as a control species in the experiments and became infected in the following ratio: Eight (66 per cent) of twelve specimens with P. vivax, and three (15 per cent) of nineteen specimens with P. falciparum.

"In determining the relative susceptibility of the three species only those individuals which had fed upon the same gamete carriers are considered. The number of mosquitoes from which the percentages are computed is too small to make the results entirely conclusive."

A bibliography of 15 titles is appended.

Anopheles punctipennis.—Its relation to the transmission of malaria; report of experimental data relative to subtertian malarial fever, M. B. MITZMAIN (Pub. Health Rpts. [U. S.], 31 (1916), No. 6, pp. 301-307).—"Two hundred and nineteen specimens of A. punctipennis were dissected from 3 to 38 days after multiple bites on individuals whose blood contained varying numbers of subtertian gametocytes (estivo-autumnal crescents). No infection was observed in the dissection of stomachs and salivary glands.

"Two healthy individuals were bitten 91 and 180 times by specimens of A. punctipennis, 4 to 33 days after sucking blood of a subtertian malarial carrier. In this experiment, and subsequently in the employment of a healthy volunteer to feed 22 additional mosquitoes of this same species, A. punctipennis could not be incriminated in the transmission of subtertian malarial fever. The negative results in this experiment check only with the negative findings in the dissections of A. punctipennis, as it is recognized that the volunteers were not under absolute control; that is, because of the possible exposure to bites from infected anophelines while living in New Orleans.

"Control feedings with 74 specimens of A. quadrimaculatus resulted in an infection of 13.8 per cent, and with three specimens of A. erucians of 33.3 per cent. The coincidence in which one person developed subtertian malaria 11 days following the single bite of an A. quadrimaculatus that had become infected (as shown by dissection) 17 days previously by biting a heavily infected carrier, pointed strongly to this as the source of infection. This might be offered as an additional check in the experiment, recognizing, however, the limitations that might be placed on it because of lack of absolute control of the volunteer living in New Orleans."

Observations on the Culicidæ, B. Galli-Valerio (Centbl. Bakt. [etc.], 1. Abt., Orig., 76 (1915), No. 4, pp. 260, 261).—This note relates to the hibernation, biology, and breeding places of Culicidæ in Switzerland.

Observations on the bionomics of Stegomyia fasciata, J. W. S. Macfie (Bul. Ent. Research, 6 (1915), No. 3, pp. 205-229).—Notes on the author's observations of the yellow fever mosquito, relating to length of life, blood feeding, ovulation, intolerance of the larvæ to common salt, etc., much of which data is presented in tabular form.

A note on treatment of swamps, stream beds, ponds, wells, pools, and other mosquito infested areas for the destruction of their larvæ, H. C. Wilson (Madras: Madras Fisheries Bur., 1914, pp. 14, pls. 8).—A note on mosquito control work in India.

Some new neotropical Simulidæ, F. Knab (Bul. Ent. Research, 6 (1915), No. 3, pp. 279-282).—Three species, namely, Simulium sanguineum from Columbia, S. limbatum from British Guiana, and S. placidum from Trinidad, are described as new to science.

Flies: A factor in, a phase of, filariasis in the horse, F. E. Place (Vet. Rec., 28 (1915), No. 1418, pp. 120-125).—The author attempts to trace a direct connection between the existence of certain flies, notably Stomoxys calcitrans, Musca domestica, and M. vetustissima, and the presence of certain filariæ in the stomach of the horse.

Chemical reactions of fruit flies, F. M. Howlett (Bul. Ent. Research, 6 (1915), No. 3, pp. 297–305, pls. 4).—"There are certain smells remarkably attractive to male flies of the genus Dacus and by the employment of these smells the movements of the flies can to a great extent be controlled in any given direction. The reaction is strictly confined to the male sex, and different species exhibit a variation as regards the smell which is most attractive to them. It is uncertain whether the females emit similar smells; on the whole improbable."

Effect of cold storage temperatures upon the pupæ of the Mediterranean fruit fly, E. A. Back and C. E. Pemberton (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 7, pp. 251-260, figs. 2).—In the investigations here reported the authors, assisted by H. F. Willard, conducted extensive experiments to determine the effect of the various ranges of temperatures used in commercial cold storage plants upon the pupæ of the Mediterranean fruit fly. The work was carried on in connection with that relating to the effect of cold upon the eggs and larval instars, previously noted (E. S. R., 34, p. 554).

In the introduction the authors call attention to the fact that while the greatest danger in the spread of this pest from one country to another lies in the transportation of the larvæ within fruits, it is possible that the pest may also be transported in the pupal stage and arrive at its destination in a condition to produce infestation. It is stated that nearly all the experimental work with temperatures lower than 45° F. was carried on in a thoroughly modern cold storage plant.

The data presented, much of which are given in tabular form and include observations on 173,318 pupæ, indicate that none survive refrigeration for longer periods than are necessary to cause the death of the eggs and larvæ in host fruits held at corresponding temperatures. "About 50° is the critical point below which development can not take place and below which death will follow if refrigeration is continued sufficiently long. At 49 to 51° only 9 out of 39,500 pupæ yielded adults in refrigeration 20 to 47 days after the inward date, while 3 out of 6 held at 52 to 56° yielded adults in refrigeration 38 to 52 days after the inward date. Many pupæ can complete their entire development in refrigeration at 54 to 57°, while higher temperatures, not considered here, merely retard development without causing noticeable mortality.

"Pupæ can not withstand temperatures below 50° for prolonged periods of time. Only 3 and 1 pupa survived refrigeration for 8 and 9 days, respectively, at 32°, while none of 4,500 pupæ survived 10 days at this temperature. Refrigeration at a temperature averaging 34°, but ranging between 33 and 36°, proved fatal after the seventeenth day; 6,017 pupæ refrigerated at this temperature for 18 and 25 days yielded no adults, while the number to yield adults after refrigeration for 14 and 17 days was very small. No pupæ survived refrigeration at 28 to 40°, but averaging 36°, for more than 10 days. A temperature of 38 to 40° proved fatal after the nineteenth day; 30,731 pupæ refrigerated for from 21 to 35 days failed to yield adults on removal to normal temperatures. After refrigeration at 40 to 45° pupæ from each of two lots

removed after refrigeration for 24 and 27 days, respectively, yielded adults; 500 pupe removed after refrigeration for from 31 to 34 days proved to be dead.

"It does not seem safe to conclude that the age of the pupa has a direct bearing upon its ability to withstand the more ordinary ranges of cold-storage temperatures."

The bean maggot in 1915, D. B. Whelan (Michigan Sta. Circ. 28 (1916), pp. 3, 4).—Serious damage was done by the bean or seed-corn maggot in Huron, Sanilac, Tuscola, Saginaw, Gratiot, Eaton, and Berrien counties in Michigan during 1915, previous to which year it had appeared in scattered numbers over quite a large area and the damage had been comparatively slight. Instances are reported of fields in which the loss of plants varied from 50 to 80 per cent. Examinations of a series of bean fields beginning on July 1 showed that the maggots had been present in the fresh manure, clover sod, and the rotting stems of clover, and had transferred their attention to the beans. The eggs are usually deposited on the stems of the plants just coming through the soil or on decaying vegetable matter.

It appears that cultural methods furnish the best means for combating this maggot. Land which is in clover or is covered with manure should be plowed early and prepared, so that the soil will be in good condition and the maggots given time to disappear before the beans are sowed. "Commercial fertilizers may be substituted for barnyard manure when the necessity for late fitting of the soil demands it, and repeated harrowing and perhaps rolling, especially when the ground is light in texture, seem to aid."

The adaptative forms of anthomyid larvæ; Anthomyidæ, the larvæ of which are carnivorous, D. Keilin (Bul. Soc. Ent. France No. 20 (1914), pp. 496-501, figs. 3; abs. in Ent. No. Mag., 3. ser., 1 (1915), No. 8, pp. 242, 243).—In continuation of investigations of dipterous larvæ the author, in dealing with the Anthomyidæ, refers to larvæ with saprophagous, phytophagous, parasitic, and carnivorous habits.

A catalogue of Coleoptera (Coleopterorum Catalogus. Berlin: W. Junk, 1913, pt. 56, pp. 223; 1914, pts. 57, pp. 289-408; 58, pp. 65; 59, pp. 215; 60, pp. 62; 61, pp. 16; 62, pp. 182; 1915, pts. 63, pp. 84; 64, pp. 14; 65, pp. 82).—In continuation of this work (E. S. R., 30, p. 458) part 56, by A. Grouvelle, catalogues the Byturidæ and Nitidulidæ; part 57, by M. Bernhauer and K. Schubert, the Staphylinidæ, IV; part 58, by M. Pic, the Dascillidæ, Helodidæ, and Eucinetidæ; part 59, by H. Clavareau, the subfamily Eumolpinæ of the Chrysomelidæ; part 60, by R. Jeannel, the subfamily Bathysciinæ of the Silphidæ; part 61, by A. Méquignon, the Rhizophagidæ; part 62, by F. Spaeth, the subfamily Cassidinæ of the Chrysomelidæ; part 63, by E. Csiki, the Mordellidæ; part 64, by S. Schenkling, the Derodontidæ, Lymexylonidæ, and Micromalthidæ; and part 65, by S. Schenkling, the Oedemeridæ.

White grubs in Iowa, R. L. Webster (Iowa Sta. Circ. 29 (1916), pp. 4, figs. 3).—This circular calls attention to the importance of white grubs in Iowa and discusses control measures.

An insect pest of lucern, C. French, Jr. (Jour. Dept. Agr. Victoria, 13 (1915), No. 9, pp. 567-569. figs. 3).—The cockchafer Heteronyx piceus has been found to be a source of injury to alfalfa at Werribee, Victoria, considerable loss resulting.

Bud weevils and other bud-feeding insects of Washington, M. A. YOTHERS (Washington Sta. Bul. 124 (1916), pp. 5-43, pls. 6, figs. 3).—This paper reports observations made of the biology and control of weevils and other beetles which have been injuring the fruit buds of one- and two-year-old fruit trees in Washington State. It appears that several of the weevils are native feeders on the

sagebrush (Artemisia tridentata), the principal host plant in the districts where they are found, the injury being brought about through the clearing up of such lands and setting them to fruit trees, which then become the only available food plant.

The injury caused by the various species is said to have been considerable; at times every bud is eaten out and the trees die or do not get a start after they are planted. At other times only a few of the buds are destroyed and the trees are able to maintain themselves. In some orchards it was found that as many as half of the young trees were killed. Although this was an unusually high percentage, it is not uncommon to find new plantings with losses of 20 per cent.

The studies in 1911 were made at four localities and during 1912 at as many as 15. A list is given of 14 weevils and 5 other beetles studied, together with tables showing the different plants upon which the various species occur, the remedies tried, and the results obtained.

In regard to methods of control it is stated that as the weevils are wingless and can not fly they can be prevented from destroying the buds by the use of paper-cone tree protectors, here described, which are the most effective and practical means of protecting the trees against the weevils. The paper cones are also effective against climbing cutworms. With a little care and attention to the adjustment of the cones they will give protection throughout the first season, which is usually as long as necessary, as the weevils do not often injure older trees.

The weevils noted are Cercopeus artemisiæ, Cleonus lobigerinus, C. quadrilineatus, Geoderces melanothrix, Melamomphus luteus, M. nigrescens, Mimetes setulosus, Mylacus saccatus, Panscopus æqualis, P. sulcirostris, Sitona apacheana, Tosastes cinerascens, Tricolepsis sp., and Tychius lineellus. The other beetles noted are Cotalpa granicollis, Eusattus muricatus, Glyptoscelis alternata, Polyphylla decemlineata, and Syneta albida.

From an economic standpoint *T. cinerascens* is the most important of the weevils discussed in this paper, being the cause of thousands of dollars of losses to orchardists throughout the whole of the arid region in the State. *M. setulosus*, the most abundant weevil, is the second most injurious of the bud weevils here discussed, having a wider distribution and a larger number of host plants than any of the other species. *E. muricatus* has been observed to travel readily up the trees and from bud to bud and can soon destroy all the buds on a tree. On older trees it feeds on the blossoms as well as the buds and young leaves and has been known to destroy the blossoms in some orchards to such an extent as practically to ruin the crop.

The strawberry weevil (Anthonomus signatus), T. J. Headlee (New Jersey Stas. Circ. 56 (1916), pp. 3-8, fig. 1).—Measures hitherto recommended for the control of the strawberry weevil having proved unsatisfactory, except in a limited way, the author was led to conduct the insecticide experiments here briefly reported, assisted by E. Douglass. While they were conducted in only one field with but a single variety of strawberry (Heritage), the results indicate what may be accomplished.

It was found that combinations of arsenate of lead and sulphur maintained as a dust coating throughout the two weeks when the strawberry is subjected to the serious attack will afford almost perfect protection. While the half-and-half mixture of lead and sulphur is the most efficient, a mixture composed of one part of arsenate of lead to five parts of sulphur is effective and much cheaper. Two applications were in this case sufficient, the first being applied just as the beetles began to damage the buds and the second as soon there-

after as the first treatment had disappeared from the upper surface of the foliage. The mixtures are readily applied with a powder gun and should coat thoroughly all parts of the plants, especially the buds. For the 1:5 mixture the cost should not exceed \$8 and for the 1:1, \$16 an acre, and in practical work this charge will probably prove to be materially less.

Some injurious Indian weevils (Curculionidæ), G. A. K. Marshall (Bul. Ent. Research, 5 (1915), No. 4, pp. 377-380, figs. 4; 6 (1916), No. 4, pp. 365-373, figs. 5).—The species described in the first paper as new to science are Phytoscaphus dissimilis, found feeding on young tea shoots, and Corigctus bidentulus, a serious pest of tea, in Assam; and Rhynchanus (Orchestes) mangiferæ, the larvæ of which bore in the leaves of the mango tree, and Pachytychius mungonis, a cowpea (Phaseolus mungo) pest, in Madras.

The new species described in the second part are *Emperorrhinus defoliator* n. g. and n. sp., found to defoliate the alder tree (*Alnus nitida*) and fruit trees; *Coniatus indicus* n. sp., which attacks tamarisk (*Tamarir indica*); *Ceuthorrhynchus portulacæ* n. sp., the larvæ of which mine the leaves of purslane (*Portulaca oleracea*) cultivated as a vegetable; *Baris portulacæ* n. sp., found boring in the stems of purslane; *Athesapeuta oryzæ* n. sp., a serious pest of rice; and *Acythopcus citrulli* n. sp., a pest of watermelons.

[Mouth parts of the honeybee], E. R. Root (Jour. Heredity, 7 (1916), No. 1, pp. 46, 47, fig. 1).—Examinations of a colony of bees that worked in red clover in full bloom showed that the tongues of this particular colony measured 0.23 and 0.24 in., whereas the tongues of normal bees measured only 0.16 and 0.17 in.

Natural swarming of bees and how to prevent it, M. Pettit (Ontario Dept. Agr. Bul. 233 (1915), pp. 15, figs. 8).—Practical information for the beekeeper.

A monograph of the Formicidæ of South Africa (Ponerinæ, Dorylinæ), G. Arnold (Ann. So. African Mus., 14 (1915), pt. 1, pp. 159, pl. 1, figs. 8).—Two of the five subfamilies of Formicidæ are here dealt with.

It is pointed out that in South Africa the Ponerinæ comprise about 20 per cent of the known ant fauna, and that since at least 80 per cent of their food consists of termites they constitute one of the chief checks to these pests in the Tropics. It is thought probable that all, or at least the majority, of the species of the subfamily Dorylinæ are carnivorous, although one species (Dorylus orientalis) has been shown to feed also upon tubers and the bark of trees. Another species (D. fulvus rhodesiæ) has apparently been found to attend membracid larvæ feeding on the roots of maize.

The acrobat ant, H. A. Ballou (Agr. News [Barbados], 14 (1915), No. 351, p. 330).—An account of Cremastogaster sp., which is abundant in different parts of Grenada and may become troublesome in cacao fields in that island.

The control of ants which take away onion seed (Agr. News [Barbados], 14 (1915), No. 354, p. 378).—A brief report of experiments conducted with a view to preventing ants from removing onion seeds when planted and from biting holes in the young shoots, as occurs in St. Vincent. In experiments conducted the most satisfactory results were obtained through attracting the ants to various baits and then killing them.

Two new species of Arrhenophagus with remarks, A. A. GIRAULT (Jour. N. Y. Ent. Soc., 23 (1915), No. 4, pp. 241, 242).

Notes on two South American parasitic Hymenoptera, A. A. GIRAULT (*Entomologist*, 48 (1915), No. 628, pp. 213, 214).—Baeus auraticeps n. sp. is recorded as having been reared in numbers from the egg sac of a spider at Anna Regina, British Guiana.

Three new British chalcidoid Hymenoptera, with notes, A. A. GIRAULT (Entomologist, 48 (1915), No. 628, pp. 217, 218).—Aphidencyrtus aspidioti brit-

tanicus n. sp. and Apterotrix longiclava n. sp. were reared from the oyster shell scale at Manchester, England.

Ticks of the Belgian Kongo and the diseases they convey, G. H. F. NUTTALL and C. WARBURTON (Bul. Ent. Research, 6 (1916), No. 4, pp. 313-352, figs. 48).-This paper, prepared at the request of the Belgian authorities, includes a brief résumé of the classification of ticks, with a short illustrated account of the species occurring in the Kongo, discussions of the general biology of ticks and the special biology of those occurring in the Kongo and their relation to disease, instructions for rearing ticks, etc.

The life cycle of Trypanosoma brucei in the rat and in rat plasma, R. ERDMANN (Proc. Nat. Acad. Sci., 1 (1915), No. 10, pp. 504-512, figs. 7).—The author's investigations have resulted in the discovery of dimorphic forms, latent or round forms, and crithidia-like forms in T. brucei outside of the invertebrate host.

FOODS-HUMAN NUTRITION.

A sanitary study of condensed milk, W. H. PARK, M. C. SCHROEDER, and P. Bartholow (N. Y. Med. Jour., 102 (1915), No. 22, pp. 1073-1083, figs. 10).-The investigation herein reported concerns the bacterial content of the milk used in preparing condensed milk; the process used in condensing milk with reference to its effect on the bacteria; and a bacteriological and chemical examination of the finished product.

Evaporated milk contained fewer bacteria than condensed milk, probably owing to the higher temperature used in its manufacture. Sweetened condensed milk showed the following variations in composition: Cane sugar, from 33.15 to 49.85 per cent; milk sugar, 7.57 to 15.34 per cent; and protein, 6.73 to 13.59 per cent.

The data of the experiments and clinical observations are summarized in part as follows:

"The value of sweetened condensed milk depends upon the care and cleanliness used in manufacture.

"There is a want of evidence that the bacteria or chemical constituents are capable of affecting the health. Only the use of the best quality of sweetened condensed milk is to be commended in the feeding of infants.

"Sweetened condensed milk, when carefully prepared from whole milk, has special indications as an infant food. They may be thus expressed: Many infants are unable to digest the fat of cow's milk, even when two or three volumes of water are added. In such cases the half digested curds of casein are vomited. The change in these circumstances to sweetened condensed milk allays the vomiting. These facts are well established clinically.

"Sweetened condensed milk has generally a constipating effect."

The opposite view that it produces diarrhea seems to be wanting in evidence. "Clinical evidence . . . [indicates] that the intestinal irritation caused by milk is an effect of the action of the liquid portion, when freed of fat, sugar, and protein."

The water content of meat products, E. Feder (Chem. Ztg., 40 (1916), No. 21, pp. 157-160).—A controversial article (E. S. R., 34, p. 365).

Annual report of the Commissioner of Fisheries to the Secretary of Commerce for the fiscal year ended June 30, 1915, H. M. SMITH (U. S. Dept. Com., Bur. Fisheries Doc. 827 (1915), pp. 83).—This report contains general information and data regarding the quantities and values of food fish products landed at various places.

Ptomaine poisoning from "creamed" codfish, M. A. BLANKENHORN, G. E. HARMON, and P. J. HANZLIK (Cleveland Med. Jour., 15 (1916), No. 2, pp. 97-104; abs. in Jour. Amer. Med. Assoc., 66 (1916), No. 15, p. 1166).—A number of cases of so-called ptomaine poisoning, attributed to the eating of creamed salted codfish, are reported.

Bacteriological examination of the creamed fish showed the presence of *Bacillus coli communis* and other saprophytes and some staphylococci, but the authors do not attribute the symptoms to infection by the organisms in the fish material. The same physiological reactions were given by extracts of the creamed fish and of the same brand of salted codfish which was allowed to putrefy and was then prepared in the same manner as the food which the patients had been eating. The purified active extract of the creamed putrefied codfish contained a physiologically active base, whose chemical reactions resembled those of the group of diamins to which putrescin, cadaverin, and histamin belong.

Suitability of different kinds of wheat for bread making, O. RAMMSTEDT (Ztschr. Öffentl. Chem., 21 (1915), Nos. 20, pp. 306-312; 21, pp. 321-329; 22, pp. 337-345).—Analytical data and baking tests are herein reported from which the author concludes in part as follows:

Small amounts of albumin and globulin are necessary in flour to give good results in baking, but too much or too little of these constituents acts unfavorably. The ratio of gliadin to glutenin influences the volume of the loaf, and the higher the total phosphoric acid content the greater the loaf volume. The water-soluble extractives also determine baking quality, and there seems to be a relationship between the carbohydrates soluble in water and the volume of the loaf.

A modified war bread, Rossmann (Chem. Ztg., 40 (1916), No. 18, p. 135).— The composition of this substance (called N-bread) is as follows: Water 44.31, ash 1.31, fat 0.2, crude fiber 0.03, protein 5.87, and nitrogen-free extract 48.28 per cent. The bread is made by mixing 217 gm. of rye or wheat flour with 56 gm. of potato flour and adding to this 200 cc. of water containing 7 gm. of nutritive yeast, 8 gm. of table salt, and from 4 to 5 gm. of yeast as a rising agent. The product contains more protein than previously noted war breads and is recommended by the author for general use even after the war.

Fruit preservation and inspection, T. ZSCHOKKE (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 588-590).—As a part of the report on fruit investigations are included the results of experiments on preserving plums and cucumbers, fruit inspection, the testing of fruit kilns, etc.

Factors which influence the quality of tea, J. J. B. Deuss (Dept. Landb. Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 42 (1915), pp. 26, pl. 1).—This bulletin contains data regarding the judgment of tea, such factors as the caffein content, the ash content, the quantities of essential oils, and the amount of stems present in the tea being considered. Some of the material has been noted from another source (E. S. R., 34, p. 166).

The dairy and pure food laws of the State of Connecticut ([Hartford, Conn.]: Off. Dairy and Food Comr., [1916], pp. 52).—The text of the laws is given as amended to the close of the legislative session of 1915.

Twenty-second annual report of the dairy and food commissioner of the State of Michigan for the year ending June 30, 1915, J. W. Helme (Ann. Rpt. Dairy and Food Comr. Mich., 22 (1915), pp. 405, pls. 11).—The various activities of the department during the year ended July 1, 1915, are recorded.

The report of the state analyst, F. L. Shannon, contains the results of the examination of 2,195 samples of miscellaneous foods and beverages, of which

445 were found to be adulterated, misbranded, or illegally sold, and also the analysis of 278 samples of feeding stuffs. The report of the drug analyst, A. R. Todd, presents the results of the examination of 558 samples of drugs, of which 134 were found to be adulterated. The work of the division of weights and measures is reported in detail. The publication also contains general information relating to pure-food topics and gives results of the inspection of dairies, creameries, cheese factories, city-milk depots, etc. A statement of prosecutions made during the fiscal year, the results of court proceedings brought, and reprints of the state food and drug laws and court decisions relative thereto are included.

Fifteenth biennial report of the Minnesota State Dairy and Food Commissioner, J. G. Winkjer (Bien. Rpt. Minn. State Dairy and Food Comr., 15 (1913-14), pp. 89, ftgs. 10).—The work of the commission for the biennial period ended July 31, 1914, is reviewed. The report of the state chemist, J. Hortvet, gives the results of the analysis of 4,181 samples of miscellaneous foods, beverages, paints, oils, etc., of which 1,885 were found to be illegal.

The lunch room, P. RICHARDS (Chicago: The Hotel Monthly, 1916, 2. ed., rev. and enl., pp. 239, pl. 1, figs. 117).—This publication contains information on plans, equipment, management, accounting, food and drink sales, and bills of fare, and gives recipes.

Feeding of prisoners of war in Germany, FRIEDRICH (Jour. Roy. Army Med. Corps, 24 (1915), No. 4, pp. 387-394).—This article is a translation of an official German order for feeding prisoners of war. Classified information is given regarding the management of camps and the regulation of supplies, including standardized menus for feeding the men.

The biochemical analysis of nutrition, C. L. Alsberg (Jour. Wash. Acad. Sci., 6 (1916), No. 10, pp. 269–280).—This lecture discusses some of the recent contributions to the knowledge of the component parts of the food elements and their fate in metabolism, especially the investigations of the rôle of the amino acids in nutrition.

Experiments on the effects of a limited diet, VII-IX, S. BAGLIONI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 11, pp. 1158-1163; II, Nos. 4, pp. 213-220; 5, pp. 254-259).—Three papers are included, continuing previous work (E. S. R., 31, p. 264).

Reporting studies of the comparative nutritive value of wheat flour, corn flour, and egg powder, feeding experiments with laboratory animals (white rats) are described, in which a standard basal ration was supplemented in turn by egg powder, wheat flour, and corn flour. The rats receiving egg powder exhibited a marked increase in body weight, while those receiving wheat or corn flour failed to show similar development.

The author concludes that the nutritive value of the protein in corn and wheat is inferior to that of the protein in egg powder. It is noted, however, that the nutritive value of zein or gliadin alone is less than that of the whole grain protein.

In studies of the modifications of the metabolism of guinea pigs by exclusive feeding of corn, wheat, or green plants, feeding experiments with guinea pigs which received an exclusive diet of these substances, with the addition of water, are reported. In most cases the animals died, though some survived on the ration of green plants and water. The results indicate, in the author's opinion, that the animals died of acidosis produced by a lack of basic salts in the ration.

The rectal and intravenous utilization of grape sugar, G. Bergmark (Skand. Arch. Physiol., 32 (1915), No. 4-6, pp. 355-404, figs. 36).—Experimental

data are reported which show that dextrose may be utilized either by rectal or intravenous injection. The excretion of acetone bodies was in some cases appreciably diminished by this treatment.

The rectal and intravenous utilization of grape sugar, F. REACH (Skand. Arch. Physiol., 33 (1915), No. 1-3, pp. 81-84, fig. 1).—A comment on the above reference.

The limit of assimilation of glucose, A. E. TAYLOR and FLORENCE HULTON (Jour. Biol. Chem., 25 (1916), No. 1, pp. 173-175).—The authors report feeding experiments with normal men who received varying amounts of glucose (from 200 to 500 gm.) from $2\frac{1}{2}$ to 3 hours after a light breakfast. Analyses of the blood and urine were made to indicate the extent of the utilization.

"Apparently there is in the majority of healthy adult males no limit of assimilation of glucose; glucosuria does not occur following the largest possible ingestions of pure glucose."

The influence of salicylate on metabolism in man, W. Denis and J. H. Means (Jour. Pharmacol. and Expt. Ther., 8 (1916), No. 6, pp. 273-283).— Experimental data are reported concerning the nitrogenous and respiratory metabolism of normal men as affected by the ingestion of sodium salicylate. The results indicate an increased excretion of nitrogen, phosphates, and uric acid, but no change in the respiratory quotient.

Beri-beri in Lebong.—An account of the steps taken to eradicate the disease during 1914, J. C. Kennedy (Jour. Roy. Army Med. Corps, 25 (1915), No. 3, pp. 268-285, figs. 2).—A clincal report of an epidemic among English soldiers, which proved to be beri-beri. The disease was eradicated by providing an adequate diet and by improving the general health of the soldiers by means of hygienic surroundings and physical exercise.

Clinical calorimetry, VI-XVII (Arch. Int. Med., 15 (1915), No. 5, pp. 882-944, figs. 9; 17 (1916), No. 6, pp. 855-1059, figs. 18).—A continuation of previous work (E. S. R., 34, p. 68).

VI. Notes on the absorption of fat and protein in typhoid fever, W. Coleman and F. C. Gephart (pp. 882-886).—Analytical data are reported showing the metabolism of protein and fat for seven typhoid patients on the high-calorie diet.

VII. Calorimetric observations on the metabolism of typhoid patients with and without food, W. Coleman and E. F. Dubois (pp. 887-938).—The calorimetric data herein reported were obtained by the use of the respiration calorimeter in Bellevue Hospital.

VIII. On the diabetic respiratory quotient, G. Lusk (pp. 939-944).—The information presented in this paper is of value in explaining metabolism in diabetes. Particular weight is attached to the relationship between the ingestion of protein and the respiratory quotient. Both normal and diabetic respiratory quotients are given for the individual amino acids.

IX. Further measurements of the surface area of adults and children, Margaret Sawyer, R. H. Stone, and E. F. Dubois (pp. 855-862).—Measurements of surface are reported, the results of which are summarized as follows:

"The so-called 'linear formula' [E. S. R., 34, p. 68] for the estimation of the surface area has been satisfactorily tested on four new subjects of varying size and shape. In addition partial measurements of two legless men have been made. The average error in the formula when applied to the four subjects was 1.3 per cent. Two of the subjects were children and in these cases the error in the formula was under 3 per cent. Since the youngest was about two years old, it does not seem advisable to use the formula for babies under this age until the factors have been tested by the measurements of infants."

X. A formula to estimate the approximate surface area if height and weight be known, D. and E. F. Dubois (pp. 863–871).—"The method of calculating the surface area from the so-called 'linear formula' is given with a slight correction in the factor for the arms and an alternative measurement for the thighs. A simpler 'height-weight formula' has been devised to estimate the surface of subjects if only their height and weight be known. This is expressed in the terms $A = W^{0.22} \times H^{0.725} \times C$, A being the surface area in square centimeters, H the height in centimeters, H the weight in kilograms, and H the constant 71.84. A chart has been plotted from this formula so that the approximate surface area may be determined at a glance."

"The errors in the various formulas [are estimated] as follows: 'linear formula' and 'height-weight formula' maximum \pm 5 per cent, average \pm 1.5 per cent, Meeh's formula $[A=W^{2/3}\times C]$, maximum + 30 per cent, average + 15 per cent. In general the maximum figures apply only to those of unusual shape, while with those of average body form the average error will seldom be exceeded."

XI. A comparison of the metabolism of men flat in bed and sitting in a steamer chair, G. F. Soderstrom, A. L. Meyer, and E. F. Dubois (pp. 872–886).—Experimental data are summarized by the authors as follows:

"The Sage calorimeter in the season of 1914–15 was fully as accurate as in the previous years. Alcohol checks gave the following total errors: Heat + 0.51 per cent, oxygen - 0.51 per cent, carbon dioxid - 0.36 per cent, water + 3.13 per cent. The respiratory quotient averaged 0.666, while the theoretical quotient was 0.6667.

"Four normal men and two cardiac patients were studied in the calorimeter lying flat in bed and in the semireclining position propped up with a back rest, or else in a comfortable steamer chair. A total of 21 experiments showed that the metabolism averaged 3 per cent lower in the semireclining posture. One of the cardiacs, and possibly one of the normal controls, showed a slightly higher metabolism when propped up in bed.

"The difference between the results is so small that in the study of pathologic cases . . . the same figures [can be used] for the average normal metabolism in both postures. In the majority of cases, however, the energy requirement is lower in the orthopneic position."

XII. The metabolism of boys 12 and 13 years old compared with the metabolism at other ages, E. F. Dubois (pp. 887-901).—"Eight normal boys, 12 or 13 years old, were studied in the respiration calorimeter four to six hours after a small breakfast. They were allowed to read for one of the two experimental hours, but were very quiet. The methods of direct and indirect calorimetry agreed within 0.04 per cent. Their heat production per unit of surface area was 32 per cent higher than the adult level according to Meeh's formula, or 25 per cent higher according to the more accurate 'linear formula.'

"In studying the effect of growth on metabolism, interpretation of the results obtained on infants is complicated by the fact that babies differ greatly from adults in the proportions of the body and the relative size of the viscera, notably the liver and thyroid. Boys just before the onset of puberty have almost adult proportions. They are in the midst of a period of accelerated growth. The fact that the metabolism is high points to a specific increase in the metabolism of the growing organism."

XIII. The basal metabolism of normal adults with special reference to surface area, F. C. Gephart and E. F. Dubois (pp. 902-914).—"The basal metabolism of four normal men and one woman has been determined, and experiments have been made on the specific action of protein and glucose.

"A study of the new controls, together with those reported in the literature since . . . [the] last publication [E. S. R., 34, p. 68], supports the views previously expressed. There is no reason to change the statement made in . . . [the] previous paper, that if a given subject's basal metabolism is more than 10 per cent from the average, it may be regarded as abnormal, but can not be proved abnormal unless the departure from the average is at least 15 per cent. The average basal metabolism of normal men is 34.7 calories per square meter per hour as determined by Meeh's formula. On account of the average plus error of about 15 per cent in Meeh's formula the average figure is 39.7 calories, or in round numbers 40 calories, when the more exact 'linear formula' or the new 'height-weight formula' is used to determine surface area.

"The average metabolism of fat and thin subjects is the same according to surface area when the surface area is correctly measured. The metabolism of women averages 37 calories, or 6.8 per cent lower than that of men. A group of men and women between the ages of 40 and 50 gave figures 4.3 per cent below, and a group 50 to 60 years old 11.3 per cent below the average for the larger group between the ages of 20 and 50.

"Under the atmospheric conditions of the calorimeter experiments the average water elimination by normal men through skin and lungs is 28.4 gm, an hour. About 24 per cent of the heat produced is dissipated in the vaporization of water.

"The figures for the specific dynamic action of protein and glucose previously obtained are confirmed. A table of normal standards is given."

XIV. Metabolism in exophthalmic goiter, E. F. Dubois (pp. 915-964).—By means of the respiration calorimeter, 37 observations were made on 11 patients suffering from exophthalmic goiter.

XV. The basal metabolism in pernicious anemia, A. L. Meyer and E. F. Dubois (pp. 965-979).—A report of calorimetric observations of basal metabolism in six cases of anemia.

XVI. The basal metabolism of patients with cardiac and renal disease, F. W. Peabody, A. L. Meyer, and E. F. Dubois (pp. 980-1009).—Clinical observations and calorimeter experiments are reported.

XVII. Metabolism and treatment in diabetes, F. M. Allen and E. F. Dubois (pp. 1010-1059).—The data of clinical observations and respiration calorimeter experiments during the treatment of six cases of diabetes are reported in detail.

The basal energy requirement of man, E. F. Dubois (Jour. Wash. Acad. Sci., 6 (1916), No. 11, pp. 347-357, fig. 1).—In this lecture the author considers the definition of the term basal energy requirement, the manner in which metabolism is studied, and the factors by which it is influenced in health and disease. Although muscular work affects metabolism to a greater extent than all other factors combined, attention is called to the very important part that diet plays in such diseases as typhoid fever, exophthalmic goiter, and diabetes.

ANIMAL PRODUCTION.

Vigor and heredity, J. L. Bonhote (London: West, Newman & Co., 1915, pp. XII+263, pls. 11, figs. 4).—This book treats of the inadequacy of present theories of heredity, prepotency, inbreeding, coloration as an index of vigor, and other related subjects.

The formation of protein in the animal body from the nonprotein substances, A. Stutzer (Fühling's Landw. Ztg., 64 (1915), No. 11-12, pp. 281-

56493°-16--6

295).—The author summarizes the results of previous investigators in feeding ammonium salts, urea, asparagin, and other protein-rich substances, to carnivora, herbivora, and omnivora.

A list of cited literature is included.

Studies in the blood relationship of animals as displayed in the compositions of the serum proteins.—V, The percentage of nonproteins in the sera of certain animals and birds, R. M. Jewett (Jour. Biol. Chem., 25 (1916), No. 1, pp. 21, 22).—In former articles of this series (E. S. R., 32, p. 861) it was assumed that the amount of nonproteins in the blood sera of all animals was about the same, but it has since been ascertained that this assumption is not accurate. The present work was undertaken to ascertain the amount of nonprotein in the blood of each kind of animal formerly studied and to correct the figures which are affected by the revised estimation of the nonproteins.

A table is given showing the refractive indexes obtained, the percentages of albumin, globulin, and total protein determined by previous investigators, and the figures as corrected by the present investigation, for the horse, ox, rat, hog, sheep, goat, cat, dog, guinea pig, hen, and duck.

The valuation of feeding stuffs, E. LAUB (Fühling's Landw. Ztg., 64 (1915), No. 15-16, pp. 377-407; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1694-1697).—On the basis of the researches of Pfeiffer, Neubauer, and Mach on the estimation of the cash value of feeding stuffs, the German Federation of Agricultural Experiment Stations adopted in September, 1913, certain resolutions. The author subjects all these conclusions to criticism and endeavors to establish the principles for a just valuation of feeding stuffs.

Comparative feeding value of green grass and hay (Mark Lane Express, 114 (1915), No. 4375, p. 145).—Experiments were conducted on the comparative feeding value of fresh grass and hay, the latter made in the ordinary way and also dried in hot-air chambers.

The effect of these fodders on milk yield was tested with three ewes and a goat, and the digestibility with the same three ewes later in the summer. The milk yield showed no constant difference in quantity or in composition between the green and dried grass, but the digestibility of fresh grass was constantly, though slightly, greater.

It is pointed out that the process of drying has a distinct influence on the nutritive value. In ordinary haymaking there is considerable loss from oxidation. This may be avoided by a rapid drying in which the initial temperature is high but does not exceed 100° C. The changes in digestibility seem to be due rather to changes of a physical nature than to chemical decomposition. They are sometimes so small as hardly to alter the proportion of starch.

The feeding of grain sorghums to live stock, G. A. Scott (U. S. Dept. Agr., Farmers' Bul. 724 (1916), pp. 14, figs. 5).—This treats of the composition and feeding value of the various grain sorghums, including analyses, and data as to methods of feeding and the value of the sorghums as forage, together with a number of suggested rations for various kinds of live stock.

In tests conducted by the Department on Texas farms grain sorghums were fed to beef cattle. The results obtained indicate the efficiency of the grain-sorghum feeds in the form of chop, head chop, silage, fodder, or stover, both in wintering cattle and in finishing them for the block. Silage of the grain sorghums was found to be very beneficial for increasing the appetites of feeders, keeping them in fine condition, and adding a high finish.

The following table summarizes the results of the work:

Results of use of grain sorghums in feeding tests on Texas farms.

Age of cattle	Number fed.	Period of feeding.	Daily ration per head on full feed.	Average daily gain per head.
				Pounds.
2 years	127	Oct. 28 to Feb. 2	Cotton-seed meal; a Kafir- corn chops; a silage.	2.39
3 years	200	Jan. 1 to May 1	Sorghum fodder;a cotton-	1.84
			seed meal, 6 pounds; Kafir- corn chops, 8 pounds; si- lage 40 pounds.	
3 years	32	••••••	Cotton-seed meal, 4 pounds; milo-maize chops, 18	1.75
			pounds; silage, 40 pounds;	
3 years	68	Jan. 17 to July 3	Sorghum butts.b Cotton-seed meal, 6 pounds;	1.75
			silage, 60 pounds; bundled Kafir corn, 6 pounds.	
20 months	90	Nov. 1 to Feb. 12	Cotton-seed meal,4.5 pounds; silage, 30 pounds; wheat	2.08
			straw.b	
Steer calves		Dec. 1 to April 16	Cotton-seed meal, 3 pounds; Kafir-corn chops, 5 pounds:	1.76
Do	63	Oct. 31 to June 4	silage, 20 pounds; straw.b Cotton-seed meal, 2.5 pounds;	1.05
D0	03	Oct. 31 to June 4	milo maize chops, 10	1.65
			pounds; silage 20 pounds; wheat straw.	
Heifer calves	116	Oct. 31 to May 1	Cotton-seed meal, 2 pounds; milo -maize chops, 5	1.38
			pounds; silage, 25 pounds;	
Do	126	Winter	wheat straw.b Cotton-seed meal, 1.5 pounds;	1.38
			milo - maize chops, 5 pounds; silage, 25 pounds;	2.00
Oalman		December Weach and de la	straw.b	
Calves		December-March, wintered only.	Cotton-seed meal, silage; straw.b	1.42

aAmounts not given.

bWere given all they would eat.

The influence of the lactic acid bacteria on protein, A. STUTZER (Biochem. Ztschr., 70 (1915), No. 3-4, pp. 299-305).—It has been found that the best fermentation in silos is obtained by using lactic acid bacteria, preferably those growing at a low temperature, as Bacillus cucumeris fermentati. In tests made by the author hay was subjected, with and without the addition of sugar, to the action of these bacteria, but the experiment showed that these bacteria are incapable of decomposing the protein present in hay. Experiments conducted to determine whether B. cucumeris fermentati has the power of forming protein synthetically by means of asparagin, urea, or ammonium acetate indicated that this is not possible.

The feeding value of apple pomace, J. B. LINDSEY (Massachusetts Sta. Circ. 58 (1915), pp. 4).—A revision of Circular 47, previously noted (E. S. R., 32, p. 363).

Beet residues for farm stock, J. B. LINDSEY (Massachusetts Sta. Circ. 62 (1916), pp. 7).—A revision of Circular 48, previously noted (E. S. R., 33, p. 267).

Analysis of feeding stuffs, B. E. Curry and T. O. Smith (New Hampshire Sta. Bul. 178 (1916), pp. 16).—Analyses are given of the following feeding stuffs: Wheat bran, wheat middlings, shredded wheat waste, red dog flour, rye middlings, cotton-seed meal, hominy feed, hominy meal, alfalfa meal, dried beet pulp, brewers' dried grains, distillers' dried grains, cracked bone, bone

meal, meat scrap, fish scrap, gluten feed, linseed oil meal, provender, oat hulls, and various mixed and proprietary feeds.

Analyses of commercial feeding stuffs, P. H. Wessels and F. O. Fitts (*Rhode Island Sta. Insp. Bul.*, 1916, May, pp. 12).—Analyses are given of the following feeding stuffs: Fish scrap, meat scrap, cotton-seed meal, linseed meal, gluten feed, dried brewers' and distillers' grains, wheat middlings, bran, provender, hominy feed, ground oats, sugar-beet meal, oat hulls, dried beet pulp, and alfalfa meal, and various proprietary and mixed feeds.

Stock raising (U. S. Dept. Int., Rpt. Comr. Indian Aff., 1915, pp. 28, 29).—A general account of the status of stock raising on the various Indian reservations. It is stated that Indian stock has been so successfully managed since the policy of increasing stock raising among the Indians was inaugurated some two years ago as to justify the undertaking fully. Inspections and reports show the tribal herds and individually owned cattle, horses, and sheep to be rapidly improving in breed, increasing in number, and showing a gratifying profit on the investment. It is predicted that the Indian-owned stock will soon become a substantial factor in the world's supply.

Cattle-feeding experiment, 1914–15, W. Bruce (Edinb. and East of Scot. Col. Agr. Rpt. Leaflet, Ser. C, No. 1 (1915), pp. 4).—In cattle-feeding experiments comparing the value of various rations (palm-nut cake, dried distillers' grains, chaffed hay and Bombay cotton cake, and Bombay cotton cake) the dried distillers' grains proved a cheaper feeding stuff than Bombay cotton cake. The results indicate that palm-nut cake (palm-kernel cake) is a useful feeding stuff and that apparently it is practically equal in value to the best class of dried distillers' grains, which it somewhat resembles in composition. It is stated that cattle do not eat this cake when it is first put before them, but that in a few days they take it quite readily, and that there appears to be no practical difficulty in feeding it to fattening steers when they are accustomed to it from the beginning of the fattening period.

Report on cattle-feeding experiments conducted at Crichton Farm, Dumfries, 1911–1915, W. G. R. PATERSON (West of Scot. Agr. Col. Bul. 67 (1915), pp. 42, pl. 1).—In three series of cattle-feeding experiments, comparing the value of decorticated and undecorticated cotton cakes, soy-bean cake, and linseed cake, decorticated cotton cake and soy-bean cake each proved superior to a mixture of linseed cake and undecorticated cotton cake, even when 1 lb. additional of the mixture was fed. The difference between decorticated cotton cake and soy-bean cake was not very great but the balance was in favor of the former. The return for every ton of oats, hay, straw, and turnips was very much greater when fed with decorticated cotton cake than when fed with a mixture of linseed cake and undecorticated cotton cake.

Palm-nut cake proved to be inferior to a mixture of decorticated cotton cake and crushed oats.

"Bulldog" cattle (Jour. Heredity, 7 (1916), No. 6, pp. 263-265, figs. 2).—An account of the Niata breed of cattle, described by Darwin. This breed is supposed to have arisen among the Indians of South America, but is now becoming extinct. The extraordinary jaw and face are thought to be due to mutation.

Mathematical selection of Swiss cattle (Breeder's Gaz., 69 (1916), No. 18, p. 958, figs. 3).—A method of appraising cattle by means of a rational mathematical system has recently been adopted by the Swiss Government. The purpose of the method is to determine and express in decimals the correlations which exist between the conformation of the different parts of the body of the animal and its fitness. The instrument deemed most practical for this is the

measuring cane invented by A. Deriaz of Lausanne. This is composed of a simple rod, grooved and graduated, and provided with two perpendicular arms, one of which is fixed permanently at one end and the other can slide along the rod and be stopped at any desired point.

The measurements taken on the animal with this instrument are as follows: (1) Measurements of the length of the body, chest, loins, and quarters; (2) measurements of the height at the withers (from the ground to the highest point on the animal), of the knee (from the ground to the lower edge of the joint), of the loin, and of the tail-head; (3) measurements of the width, by means of the two arms of the instrument, of the hooks, pin bones, and thighs; and (4) measurements of the head, principally its length, its width between the base of the horns, and the width of face.

The Yunnan breed of sheep, A. Hallot (Bul. Écon. Indochine, n. ser., 18 (1915), No. 112, pp. 165-181; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1512-1514).—An account of the breed characteristics and utility value of the sheep of Yunnan, China.

The fleece is white, black or white with spots of fawn, red, or black. With the exception of a tuft of long hair hanging over the forehead, the fleece extends from the base of the neck to the knees and above the hocks. No wool occurs on the belly, but hair often occurs under the chest, extending toward the withers. With certain rare exceptions the wool is mixed with kemp in variable quantity. In the tallest animals the base of the fleece consists of long stiff hairs.

The wool fiber and certain phases of scouring and loose wool dyeing, L. J. Mátos (Bul. Nat. Assoc. Wool Manfrs. 45 (1915), No. 2, pp. 146-171, figs. 10).—Methods of scouring and dyeing wool are described.

Fattening lambs, J. M. Jones (*Texas Sta. Bul. 186* (1916), pp. 3-15, figs. 4).—Two lots of about 250 47-lb. range-bred lambs were fed 119 days as follows: Lot 1, cotton-seed meal, cotton-seed hulls, and feterita and sorghum silage; lot 2, cotton-seed meal and feterita and sorghum silage. After 59 days of the test feterita and milo-maize chops were added to the ration of lot 2; and after 102 days the ration of lot 1 was supplemented by the same concentrate.

The results indicate that good silage can be fed to fattening lambs without injury to them. During the first 59 days the lambs in lot 2 consumed an average of 3.78 lbs. of silage per head daily and their average daily gain was 0.285 lb. per head.

"While silage seems to have a place in the ration of a fattening sheep it should not constitute the only roughage. Owing to the succulent nature of silage, it is quite impossible for lambs to consume enough of this feed to get the necessary amount of dry matter that is required by the animal body. Lambs receiving silage as the sole roughage are inclined to go 'off feed.' The lambs in lot 1 received cotton-seed hulls in addition to the silage, and throughout the entire feeding period all the lambs remained continually 'on feed.' No moldy silage was fed to the lambs and no losses directly attributed to the feeding of inferior silage resulted."

The lambs in lot 1 made a good economical gain during the early part of the feeding period, but after about 100 days they apparently became "burned out," the average daily gain per head during the final 17 days of the test being only 0.068 lb.

During the first 6 days after the feterita and milo maize had been supplied in the ration of lot 2 at the end of the first 59-day period, the average gain per head was increased from 0.24 to 0.42 lb. daily. After ground feterita and milo maize had been supplemented in the ration received by lot 2 the lambs did not go "off feed" as readily as when on the ration composed wholly of cotton-seed meal and silage.

The lambs of lot 1 returned a profit of \$1.03 per head, and those of lot 2 82 cts. per head.

The influence of domestication on the mechanical qualities of the pars compacta of Sus scrofa domestica, together with a discussion of the theory of the functional adaptation of the skeleton, A. Schmidt (Arch. Entwickl. Mech. Organ., 41 (1915), Nos. 3, pp. 472-534, pls. 2, figs. 5; 4, pp. 605-671, figs. 8).—Data are given on the moduli of strength of the compact bone substance of wild and domestic swine.

In general, grazing animals show a higher modulus of elasticity and a greater firmness than those of the same age not on pasture. The specific gravity of the compacta of *S. scrofa domestica* undergoes various changes. In the metatarsal bones of the young and the tibial and metatarsal of older wild swine it is much higher than for domestic swine of the same age. The specific gravity of the compacta of Sus and Cervus is lower in the metatarsus than in the tibia.

A bibliography of references is included.

Physiology and bacon curing, K. J. J. Mackenzie and F. H. A. Marshall (Jour. Roy. Agr. Soc. England, 76 (1915), pp. 1-13).—It is stated that the black pigment so often found in the mammary area of sows belonging to colored breeds is in no way related to sexual changes occurring during the period of heat or estrus. On the other hand, it is closely similar to, or identical with, the pigment of the hair, and is consequently harmless. It follows that the heavy losses sustained by bacon manufacturers owing to the presence of this pigment have been incurred unnecessarily.

Experiments have shown that the results of ovariotomy are such as to justify the operation being carried out for commercial purposes, since spayed sows tend to feed better and fatten faster than open or unoperated ones. Those cases in which sows which were supposed to have been spayed have behaved as though they were open are the result of faulty operating.

The breeding and feeding of pigs for bacon factory purposes, R. C. SIMMONS (Rhodesia Agr. Jour., 13 (1916), No. 2, pp. 187-214, pls. 2, figs. 3).—A general discussion of the type of pig required for bacon production, and of methods of feeding, care, and management, together with a number of suggested rations.

Feeding potatoes to fattening swine, W. Völtz (Deut. Landw. Presse, 42 (1915), No. 91, pp. 771-773, figs. 8).—It was demonstrated that it is not feasible to feed potatoes alone to growing and fattening swine, a protein supplement being essential to satisfactory development.

Feeding experiments with straw meal and cellulose material, SCHNEIDE-WIND (Landw. Wchnschr. Sachsen, 18 (1916), No. 7, pp. 57-59).—The addition of a cellulose feed, composed of 65 per cent of straw material, 20 per cent of dried potatoes, and 15 per cent of molasses, to the ordinary grain ration for swine proved to be a valuable supplement, materially increasing the gain over a grain ration alone.

Feeding pigs on the subcutaneous matter of hides intended for tanning, W. Ellenberger and W. Grimmer (Berlin. Tierürztl. Wehnschr., 31 (1915), No. 32, pp. 373-378).—The authors conducted experiments in feeding the subcutaneous matter of hides to swine. This feed was well liked by the pigs and produced normal development. It was found to be an excellent concentrated feed, equal in nutritive value to a mixture of crushed beans and vetches. The digestability of the protein was 21 per cent and the starch equivalent 76.4 per cent. The flesh of the swine was found to be normal in composition. The meat when cooked had an excellent flavor and in no case was any disagreeable taste detected, whether raw or cooked.

The composition of the subcutaneous matter is given as water 13.2 per cent, protein 55, fat 26.5, and ash 5.2.

Color in horses, J. W. Thompson (*Breeder's Gaz.*, 69 (1916), No. 19, pp. 1020, 1021).—The author presents data tending to show that English racing records demonstrate that bay is predominantly a color of speed and bottom.

Licensed stallions in Utah during the season of 1915, W. E. CARROLL (*Utah Sta. Circ.* 19 (1916), pp. 3-20).—Tables showing the distribution of licensed stallions by counties and breeds for the State of Utah are given.

Capsule method of breeding mares, W. E. CARBOLL and H. J. FREDERICK (*Utah Sta. Circ. 20* (1916), pp. 3-6, fig. 1).—This circular treats of the advantages and methods of capsule breeding of mares.

Better horses for Utah, W. E. CARROLL (*Utah. Sta. Circ. 18 (1916)*, pp. 3-10, fig. 1).—This circular treats of the number and prices of horses in the United States, the type of horse most in demand, the need of improvement, and the Utah stallion license law as a factor in the improvement of horses.

Some fertility experiments, B. F. KAUPP (Poultry Item, 18 (1915), No. 2, pp. 6, 7, 86-90, fig. 1).—Extensive data collected at the North Carolina Experiment Station indicate that under ordinary conditions a fertility of from 80 to 90 per cent should be obtained and that from 80 to 90 per cent of the fertile eggs should hatch. Fertility rapidly declines after the removal of the cocks. It is not advisable to save eggs for hatching after the male birds have been removed from the pen for five days. If the hens mated have been running with mongrel cocks all spermatozoa in the oviducts of the hens should be dead by the eighteenth day, thus making it safe to save the eggs after that time.

[Poultry husbandry] (Minnesota Sta. Rpt. 1915, pp. 41, 42).—It has been found that the labor cost per pound of raising chicks is greater before they are placed on range than afterward, but contrary to the opinion of some the food cost per pound is greater with the larger chicks. Chicks artificially hatched and reared were fed at less cost than when reared by the natural process, that is, when the cost of feeding the mother hens was reckoned with the cost of feeding the chicks. With a plentiful supply of skim or sour milk the feed cost per pound of chicks five weeks old or less varied from a little over 4 cts. to a little over 6 cts.

Results of experiments indicate that a confined area for breeding flocks results in an excess of infertile eggs and chicks of less vitality. Several trials with eggs from flocks confined to small yards compared with those from flocks that had free range, at least half the time, showed more than twice the percentage of infertile eggs from the flocks in the small yards.

Teaching the young stock to roost, Mr. and Mrs. G. R. Shoup (Washington Sta., West Wash. Sta. Mo. Bul., 4 (1916), No. 2, pp. 10-14, ftgs. 5).—The use of a modified King ventilating system and a forced roost apparatus is described, and plans for their construction are given.

Report on experiments on the feeding of poultry and on the feeding of chickens and ducklings conducted during 1913-14, Agnes Kinross (West of Scot. Agr. Col. Bul. 66 [1915], pp. 22).—Data are given on the cost of keeping poultry, the feeding of chickens from birth to a laying age, the feeding of table chickens from birth to a marketable age, and the feeding of table ducklings.

Buttermilk cheese versus meat meal in broiler duck raising, B. F. KAUPP (Poultry Item, 18 (1916), No. 7, pp. 8-10).—Three lots of ducks were fed the following rations: Lot 1, wheat bran, corn meal, and buttermilk cheese, 2:4:2; lot 2, wheat bran, corn meal, and beef scrap, 2:4:1; and lot 3, wheat bran, corn meal, and buttermilk cheese, 2:4:3.

The buttermilk cheese was made as follows: The fine-grained curd resulting from pasteurizing sour cream was brought into solution by a small quan-

tity of sodium hydroxid. The buttermilk was then curdled by acidifying with hydrochloric acid, and the vat of milk was heated to from 130 to 140° F. and held at this temperature for from 30 minutes to one hour. The curd was then drained, salted, and packed. The yield of finished cheese was about 12 per cent, and contained 20 per cent of protein.

At 10 weeks of age the average weight of lot 1 was 4.31 lbs. per head; of lot 2, 5.25 lbs., and of let 3 4.62 lbs., so that the buttermilk cheese apparently did not take the place of the meat scrap. In the 10 weeks lot 1 consumed 31 lbs. of mash which cost \$8.78, and lot 2 101 lbs. of mash which cost \$2.34. The average weight of lot 3 at the end of 11 weeks was 5.41 lbs. During this time there was consumed 429 lbs. of mash which cost \$13.21.

The high cost of the buttermilk cheese was one cause of the high cost in lots 1 and 3. If the cheese could be produced on the farm from nonsalable buttermilk, that is, buttermilk for which there is no immediate market, the cost would be merely that of converting this animal protein into a salable product, as in chick feeding.

How to start a mink ranch, R. Lewis (*Medical Lake, Wash.: Author* [1916], pp. 6).—This pamplet deals with the principles of starting a fur farm for raising mink.

DAIRY FARMING-DAIRYING.

Manual of the dairy industry, E. DE VEVEY (Lausanne: Soc. Lait. de la Suisse Romande, 1916, 2. ed., rev., pp. 340, pls. 5, figs. 110).—This book treats of the production of milk, butter, and cheese for commercial purposes.

Balanced rations for dairy stock, J. B. Lindsey (Massachusetts Sta. Circ. 63 (1916), pp. 8).—A revision of Circular 50, previously noted (E. S. R., 33, p. 275).

Studies on aerobic spore-bearing nonpathogenic bacteria, J. S. LAWRENCE and W. W. Ford (Jour. Bact., 1 (1916), No. 3, pp. 273-319, pls. 26).—This reports a morphological study made of the following spore-bearing bacteria in milk: Bacillus cereus, B. subtilis, B. albolactus, B. vulgatus, B. mesentericus, B. fusiformis, B. petasites, B. cohærens, and B. terminalis.

Electrical treatment of milk for infant feeding and the destruction of Bacillus tuberculosis, J. M. Beattie and F. C. Lewis (Jour. State Med., 24 (1916), No. 6, pp. 174-177).—In experiments with tuberculous milk it was found that electrical conditions which give at the outlet of the lethal tube a constant temperature of from 63 to 64° C. are satisfactory for the destruction of tubercle bacilli, even when these are present in such abnormal numbers as in the special sample on which the experiment was conducted.

It is concluded that the electrical method can be used successfully, but that there must be a strict adherence to certain definite conditions of measurement, rate of flow, current, density, etc.

Pasteurization in the dairy industry, O. F. Hunziker (Cream. Jour., 27 (1916), No. 9, pp. 18, 19, 22, 29; Milk Dealer, 5 (1916), Nos. 9, pp. 4-8; 10, pp. 16-20; Cream. and Milk Plant Mo., 4 (1916), No. 10, pp. 11-17).—This article deals with the commercial value of pasteurization, its germ-killing efficiency, and its effect upon flavor.

Standardizing cream (Milk Dealer, 5 (1916), No. 9, p. 22).—An accurate and simple method of standardizing cream, devised by the Dairy Division of the U. S. Department of Agriculture, is described.

Why the fat standard should be used, Hepburn (Cream. Jour., 27 (1916), No. 10, pp. 12, 13, 15).—The author urges the substitution of the fat for the moisture standard in determining the market value of butter. It is stated

that a fat standard would standardize all manufacture, as far as composition is concerned, and put purchasing and selling on a similar basis. The fat standard would practically regulate other constituents in butter and, by resulting in a decrease of the percentage of salt, would operate in such a way as to furnish the consumer with a milder piece of goods. This, it is thought, would increase the consumption of butter, as more butter would be consumed if of mild flavor.

Methods for testing butter fat are given.

Butter profits and losses (Wallaces' Farmer, 41 (1916), No. 19, p. 732, fig. 1).—A chart is given showing the estimated profits and losses for the past ten years of the dairyman who makes butter or sells cream to the creamery. The butter profit and loss areas follow very closely the business profit and loss area as devised by the Babson Statistical Organization, as do also the accompanying profit and loss areas in hogs and cattle.

American cheese in England, J. G. Foster, E. E. Young, and W. H. Bradley (U. S. Dept. Com., Com. Rpts., No. 129 (1916), pp. 836-838).—A review of some of the criticisms voiced by British importers of American cheese.

Report on the work done during 1913 at the Åtvidaberg Dairy Bacteriological Institution (Nord. Mejeri Tidn., 31 (1916), No. 3, pp. 28, 29).—In experiments at this establishment it was found that with Bacterium glycerini only 4 cheeses out of 25 gave better results than the control cheese, the rest being similar or poorer. Cheese in which albumin-dissolving cocci were introduced had excellent consistency. Using B. curvatum in Herrgård cheese gave a better taste and consistency than in the control cheeses. With B. glycerini in household cheese no effect was noticed.

VETERINARY MEDICINE.

Diseases of domestic animals and poultry, their cause, symptoms, and treatment, C. J. and A. W. Korinek (Portland, Oreg.: Korinek Remedy Co., [1915], pp. 192, figs. 24).—A popular work.

Tropical medicine and hygiene.—II, Diseases due to the metazoa, C. W. DANIELS (London: John Bale, Sons & Danielson, Ltd., 1914, pt. 2, 2, ed., pp. VIII+278, pl. 1, figs. 107).—A revised edition of part 2, previously noted (E. S. R., 24, p. 479), including a chapter on snakes, by A. Alcock (pp. 219-269).

Veterinary handbook and visiting list, T. B. ROGERS (*Philadelphia and London: J. B. Lippincott Co., 1916, pp. 119*+[96]).—This pocket handbook is planned to bring together the information needed for ready reference by the practicing veterinarian (pp. 1-119). Ninety-six blank pages ruled for a visiting list are attached.

Report of the director of the veterinary institute, Sohns (Jaarb. Dept. Landb., Nijv. en Handel Nederland. Indië, 1914, pp. 254-279).—This report contains a tabulated summary of the mallein and tuberculin distribution, together with comments on the prevalence of the diseases.

The occurrence and treatment of hemorrhagic septicemia, anthrax, swine fever, trypanosomiasis, piroplasmosis, and tetanus are briefly described. A short review of the veterinary course offered at the institute is included.

Reports of Drs. Veranus A. Moore, Mazÿck P. Ravenel, and William T. Sedgwick upon the federal meat inspection (U. S. Dept. Agr., Office Sec. Circ. 58 (1916), pp. 10).—This consists of reports submitted by experts outside of this Department, who were requested by the Secretary in July, 1913, to investigate the meat inspection work. Recommendations suggested are included.

Anesthesia and narcosis of animals and birds, F. T. G. HOBDAY (London: Baillière, Tindall & Cox, 1915, pp. XI+86).—Particular attention is given to anesthesia of the horse and dog.

The effect of chloroform on the factors of coagulation, G. R. Minot (Amer. Jour. Physiol., 39 (1915), No. 2, pp. 131-138).—"Antithrombin is rendered inactive by chloroform and ether, thus allowing free thrombin if present in an oxalated plasma to clot fibrinogen. Prothrombin is not converted to thrombin by chloroform. Chloroform can precipitate both fibrinogen and prothrombin from an oxalated plasma. Chloroform does not weaken the action of a solution of pure thrombin. Ether does slightly. Antithrombin could not be recovered from chloroform or ether extracts of serum or plasma, unheated or heated to 60° C., and is not exactly identical to antitrypsin or to Doyon's antithrombin. In one chloroform-poisoned rabbit the antithrombin of the blood was decreased below normal."

The antiseptic action of substances of the chloramin group, H. D. DAKIN, J. B. COHEN, M. DAUFRESNE, and J. KENYON (*Proc. Roy. Soc. [London], Ser. B*, 89 (1916), No. B 614, pp. 232-251; abs. in Brit. Med. Jour., No. 2880 (1916), p. 388).—The results of investigations have led to the following deductions:

"Almost all of the substances examined containing the NCl group possess very strong germicidal action. The presence in the molecule of more than one NCl group does not confer any marked increase in germicidal power. . . . The germicidal action of many of these chloramin compounds is molecule for molecule greater than that of sodium hypochlorite. Thus p-toluene sodium sulphochloramid with a molecular weight for the crystallized salt of 261.5 is as active as sodium hypochlorite with a molecular weight of 74. Substitution in the nucleus of aromatic chloramins by Cl, Br, I, CH₃, C₂H₅, or NO₂ groups does not lead to any very great increase in germicidal activity. More commonly there is a moderate diminution.

"The chloramin derivatives of naphthalene and other dicyclic compounds of the sulphochloramid type closely resemble the simpler aromatic chloramins in germicidal action. The few bromamins examined show a slightly lower germicidal action than the corresponding chloramins, but the sodium sulphobromamids are much more active than sodium hypobromite. It is significant that they react much more readily with amino acids and proteins than does sodium hypobromite. Derivatives of proteins prepared by the action of sodium hypochlorite and containing NCl groups are strongly germicidal. Blood serum inhibits their germicidal action to much the same extent as it does with sodium hypochlorite or the aromatic chloramins."

Chloramin, its preparation, properties, and use, H. D. Dakin, J. B. Cohen, and J. Kenyon (*Brit. Med. Jour., No. 2874 (1916)*, pp. 160-162).—This paper deals with the properties, practical uses, preparation and cost, and mode of action of chloramin.

Contribution to the study of immunity, F. D'HERELLE (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 15, pp. 570-573).—Experimental data submitted indicate that micro-organisms killed by certain essential oils, especially oil of mustard, constitute a reliable vaccine capable of producing an immunity in an animal against a disease to which it is naturally susceptible. The organism used in the experiment reported was Bacillus typhi murium. A single injection of the vaccine was sufficient to confer an immunity which enabled the animal to resist an inoculation of many times the lethal dose of the virulent organism.

A vaccine was also prepared by killing the micro-organism with quinin hydrochlorid, but its power to confer immunity was only relative.

Quantitative tests on the persistence of chemotherapeutic substances in the blood of man and animals, E. BOECKER (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 2, pp. 148-166).—In the blood of men, rabbits, guinea pigs, and horses, previously injected with salvarsan, a large part of the therapeutic agent was still present after one to two hours, and in the rabbit

very often after 24 hours. Optochin disappeared much more rapidly, but was still present in the guinea-pig serum two hours after an injection. It is indicated that the cellular blood elements may fix optochin to a certain degree and later release it. Formaldehyde and "rhodaform" could not be determined in the blood shortly after injection, nor could the latter be found in the bile. It is concluded that such experimental results indicate the best methods of administering therapeutic agents and the varied action of such substances in different animal species.

Further observations on the action of chemotherapeutic substances in vitro, O. Schiemann (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 2, pp. 167-187).—Salvarsan and optochin were found to be active in bouillon as well as in the serum and blood of different animals, not only in preventing the growth of the organisms but also as bactericidal agents. The inhibition of growth, however, was found to be more regular and to be valuable in determining the selective action of such substances on various organisms. The use of serum and blood of various species often yielded widely different results.

Glanders bacilli were markedly influenced by salvarsan in in vitro experiments.

The curative doses in animal experiments which alone influenced infections were such as not only prevented growth but were also sufficient for killing the micro-organisms. This difference of rapidity of action in vivo and in vitro is attributed to the slow action of the therapeutic substance and to its greatly diminished concentration in the blood stream. The results of treatment of chicken cholera infection with quinin as described by Hallenberger (E. S. R., 30, p. 286) could not be corroborated in experiments with chickens and rabbits.

Studies on antileucocytic animals, Lippmann (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 2, pp. 107–122).—Two papers are presented.

I. The mode of action of antibacterial sera and chemotherapeutic substances.—The experimental data have shown that the intravenous injection of a bacteriotropic serum (Neufeld's pneumococcus serum) may prevent the passage of the disturbing organism into the blood stream of healthy animals. Animals treated with thorium X, however, develop a bacteriemia within eight hours. The pneumococcus serum, therefore, only prevents a pneumococcus sepsis in the presence of leucocytes.

Bacteriolytic sera (cholera) show in leucocyte-free animals in the presence of complement the same bacteriolytic action (vibriolysis) in Pfeiffer's experiment as normal animals. For bacteriolysis the leucocytes are apparently of no particular importance. Protozoa are also destroyed by chemotherapeutic agents (salvarsan) the same as in normal animals.

Contrary to these results optochin (ethylhydrocuprein) was found not to prevent a bacteriemia in animals treated with thorium. Optochin thus appears to require the assistance of the entire organism for its effective action.

II. Contribution to the recognition of natural immunity against swine erysipelas.—In guinea pigs injected with swine erysipelas whose leucocytes had been destroyed by thorium X the pathogenic organisms could not be established bacteriologically, while all the normal animals died from a severe bacteriemia.

It is suggested that such curative action is due to the liberation of bactericidal substances (leukins) from the dissolved leucocytes, just as the cholera vibriolysis in Pfeiffer's experiment is accelerated through the liberation of leucocyte substance by treatment with thorium,

The biological significance of unsaturated fatty acids, J. W. Jobling and W. F. Petersen (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 24 (1915), No. 3, pp. 292-310).—It is shown that through the removal of the antiferment of the

antigen a greater toxicity is bestowed on the antigen, and that an increase of the antiferment titer in sensitized animals is associated with an increased resistance against anaphylactic shock.

Bacterial antiferments are thought to consist of unsaturated lipoids of the organisms, and the absolute resistance of intact organisms probably depends on a potential lipoid envelopment. Microchemical analysis revealed no increase of nonprecipitatable substances during bacteriolysis.

Complement and serum protease are not deemed identical.

The presence of protease was established in the serum of the guinea pig and rabbit. It was active in weakly acid and in alkaline solutions. Its action was markedly retarded at 56° C. and completely inhibited at 70°, was retarded by unsaturated soaps, and was nonspecific.

It is indicated that the Abderhalden reaction is accompanied by an adsorption of serum and a ferment. Specific tissue is not cleaved in the reaction, but the cleavage products originate from the serum proteins.

In the treatment of pathological cases with potassium iodid there is a constant lowering of the antitryptic titer by which the proteolytic ferments of the organism become more active. It is deemed possible that the therapeutic action of potassium iodid depends on this lowering of antiferment content.

On the serological action of boiled and unboiled milk and milk proteins, A. Versell (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 3, pp. 267-291).—Complement-fixation tests with human, cow's, and goat's milk have shown that human milk antisera react with cow's milk and, to a slight extent, with goat's milk. Cow's milk antisera also react with human milk. In a similar manner cow's milk casein antisera and heated cows' milk antisera react with human milk casein and boiled human milk. Contrary to this, there is no reaction between human serum antisera and cow or goat serum, or between cow serum antisera and human serum. The antisera obtained by the injection of milk serum and the casein react much stronger with the whole milk than with the respective constituents used for immunization. Whole milk and milk serum antisera, even in very small quantities, cause complement deviation with the blood serum of homologous animals. The casein and heated milk antisera do not cause this deviation. Antisera obtained by the injection of boiled milk and the constituents of boiled milk showed, in general, a weaker reaction than those obtained by the injection of the raw milk and its constituents.

Of the individual constituents of milk, the milk serum shows specific characteristics as does blood serum. The animal specificity of the casein is not so regular.

It is indicated from the experiments that a specificity of milk may be considered in the sense of "organ specificity," which is principally attributable to the casein content.

The formation of specific proteoclastic ferments in response to introduction of placenta, Florence Hulton (Jour. Biol. Chem., 25 (1916), No. 2, pp. 227–230).—"Placental protein is not digested to any greater degree by the serum of an animal sensitized to placenta than by the normal serum. The digestive power of the serum of an animal sensitized to placenta is not increased for casein, Bence-Jones protein, phaseolin, edestin, soy-bean globulin, or milk albumin. Casein is digested to a marked degree by the normal serum, and in most cases the normal serum possesses the more marked activity. Protamin is digested to a marked degree in both cases, the injected animal showing increased activity. Gliadin is not digested to any great extent by the normal serum, but is by the serum of the injected animal. In general, it may be said

that the injection of placenta does not increase the general or call forth the specific proteoclastic ferment of the blood."

See also a previous note (E. S. R., 35, p. 179).

The Wassermann reaction in rabbits after injection with luctic liver extracts, H. Eiken (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 2, pp. 188–198).—The injection of aqueous extracts or emulsions of luctic liver into rabbits yielded positive Wassermann reactions sooner or later, depending on the individuality of the extract. The reaction, in general, disappeared rather rapidly, but could often be obtained months after the injection. The same results were obtained by using an alcoholic extract of an aqueous extract of luctic liver. These results confirm the findings of earlier investigators.

A positive Wassermann reaction could not be obtained, however, by the injection of an alcoholic extract of human heart or an aqueous extract of the liver of nonsyphilitic children.

If the aqueous extracts were passed through a Chamberland filter their antigenic value was greatly reduced.

Some poisonous plants of Idaho (*Idaho Sta. Bul. 86 (1916*), pp. 16, figs. 7).—Brief descriptions are given of some of the more important poisonous plants of Idaho by F. W. Gail and some suggested remedies by A. R. Hahner.

Prevention of losses of live stock from plant poisoning, C. D. Marsh (U. S. Dept. Agr., Farmers' Bull. 720 (1916), pp. 10).—This supersedes Farmers' Bulletin 536, previously noted (E. S. R., 29, p. 280). It is pointed out that while something may be accomplished by the application of medical remedies to sick animals the main reliance in reducing losses must be upon careful management of the range and the animals upon it. Such "management should be directed to the destruction of the poisonous plants in some cases; the use of the range when the plants are not poisonous in other cases; the allotment of some ranges to animals not affected by the plants; care in driving live stock and bedding places for sheep; the elimination of fixed driveways; and to 'rotation' in the use of the range."

Acidosis and cotton-seed meal injury, C. A. Wells and P. V. Ewing (Georgia Sta. Bul. 119 (1916), pp. 35-64, figs. 2).—An account is given of the performance and results of an investigation conducted at the station during 1914 and 1915, the object of which was to determine the excess of acid-forming over baseforming elements in cotton-seed meal, and whether such excess causes the injury of pigs which have eaten large quantities of the meal.

The literature relating to the subject is first reviewed, in connection with which is given a bibliography of 215 titles. The investigation, which is reported in detail and includes much tabular data, is summarized as follows:

"One hundred gm. of cotton-seed meal contained an excess of acid-forming over base-forming elements equivalent to 8.21 cc. normal acid. A 30 to 40 day lethal dose of the cotton-seed meal was found to be 25 gm. of meal per kilogram live weight daily for 6-weeks-old pigs, weighing 6 to 10 kg. each, in the type of ration here fed. In feeding cotton-seed meal to ascertain its degree of injury, it seemed necessary to balance the ration, not so much as regards the nutritive ratio, but rather as to the necessary food factors, with some such substance as skim milk. The injury was manifested before death by rather constant abnormal physical and metabolic processes. As much as twice the mineral acid represented by the excess acid in a provisional lethal dose of cotton-seed meal did not injure the pigs, though it produced the metabolic changes characteristic of acidosis.

"Under the influence of cotton-seed meal injury the pigs did not deflect ammonia from urea formation to neutralize any excess acid in the food. The feeding of sodium bicarbonate did not prevent the injury. Addition of ferrous sulphate retarded the injury. It is concluded that acidosis played only a small part, if any, in the injury produced.

In a restricted ration, such as used in one series, pigs were seriously injured or killed within four to six weeks by eating digester tankage in amounts of nitrogen equivalent to that in a provisional lethal dose of cotton-seed meal, which was approximately 15 gm. nitrogen daily for each pig. This would indicate that, if cotton-seed meal is fed in a restricted ration and in large quantities, the ration may injure and kill pigs, even though it should contain no specific toxic substance."

On the intermediate host of the lung distome, Paragonimus westermani, S. Yoshida (Jour. Parasitology, 2 (1916), No. 3, pp. 111-118, pl. 1).—"In Formosa Nakagawa found the encysted larvæ in two fresh-water crabs and experimentally proved that they grew up to the lung distomes. The two crabs were identified by A. Terao as follows: Potamon (Geothelphusa) obtusipes [P. (Geothelphusa) dehaanii]. Nakagawa added that a fresh-water crab (Eriocheir japonicus) will also probably prove to be the intermediate host.

"I have experimentally proved that the encysted larvæ of this worm are found in three species of fresh-water crabs from various districts of Japan proper. They are identified as follows: P. dehaanii, Sesarma dehaanii, and E. japonicus."

Are sarcosporidia aberrant forms of cnidosporidia of invertebrates? B. Galli-Valerio (Jour. Parasitology, 2 (1916), No. 3, pp. 126-128).—"The observations of Piana and Galli-Valerio to the effect that spores of sarcosporidia produce amebic bodies in cultures more closely relate the sarcosporidia to the cnidosporidia. If true that sarcosporidia are only aberrant forms of neosporidia of invertebrates, then the hypothesis of Darling becomes more probable."

The preparation of tetanus antitoxin, E. H. RUEDIGER (Philippine Jour. Sci., Sect. B, 10 (1915), No. 1, pp. 31-63, figs. 85).—From the results obtained, the authors conclude that "a suitable strain of the bacillus of tetanus will usually produce potent toxin when grown in nearly neutral glucose broth under hydrogen. The acidity of the broth will rise to more than two per cent normal acid, and it should be neutralized with sodium hydrate before it is injected into the horse. Potent tetanus toxin was obtained by the method described by Ivan Hall.^a By this method the acid is continuously neutralized by the magnesium carbonate present.

"Horses differ greatly in the power of producing tetanus antitoxin." Of eight horses reported on, one produced 150 units, two 300 units, one 350 units, one 400 units, and three 500 or more units of tetanus antitoxin per cubic centimeter of serum. The antitoxin curve reached its highest mark in from six to nine months after the beginning of immunization.

"The injection of large doses of toxin is not indicated. The dosage should be such that the horse does not appreciably lose in weight."

The conjunctival tuberculin reaction, Besnort and Cuillé (Rev. Gén. Méd. Vét., 25 (1916), No. 289, pp. 9-17, fig. 1).—The authors have found the conjunctival tuberculin reaction for the detection of bovine tuberculosis of great diagnostic value and equal to the classical subcutaneous reaction. The technique is simple and rapid and has the advantage of not causing great rises in temperature. The possibilities of diagnostic error are considerably reduced. The procedure is valuable both in investigational and in practical routine work. The authors believe that it should be substituted for the subcutaneous method, the latter being reserved exclusively for the control of uncertain cases.

^a Univ. Cal. Pubs., Path., 1913, No. 2, p. 98.

Note on the stage of Piroplasma bigeminum which occurs in the cattle tick, Margaropus annulatus, H. Crawley (Jour. Parasitology, 2 (1915), No. 2, pp. 87-92, fig. 1).—"A parasitic protozoan was found in smears made from female cattle ticks (M. annulatus) and from crushed eggs which they had deposited. The parasite has the form of a minute polycystid gregarine, and is believed to represent the stage of P. bigeminum occurring in the tick. It is essentially like the form figured and described by Koch as present in engorged female ticks and their eggs, and also like the form of P. canis found by Christophers in Rhipicephalus sanguineus. In the present case, it is of interest to note that the female ticks in which the parasites were found showed an unusual mortality, suggesting that the parasite is pathogenic for the tick as well as for the cow. In addition to the gregarinoid parasite a spirochete was found in the ticks. This parasite, not heretofore reported from the United States, is perhaps the same as the form known as Spirochæta theileri."

Roundworms in poultry, life history and control, W. B. Hebms and J. R. Beach (California Sta. Circ. 150 (1916), pp. 7, figs. 3).—A series of control experiments with Ascaris inflexa was conducted by the junior author in order to test the value of certain anthelmintics and other remedies, such as powdered areca nut, powdered pomegranate root bark, turpentine, gasoline, iron sulphate, and tobacco. These were given both alone and in various combinations in the form of pills or mixed with food.

Tobacco stems when finely chopped, steeped in water for two hours, and the stems and liquid mixed with the mash were readily eaten by the fowls and gave uniformly good results. The fowls which were very badly infested with roundworms were in most instances entirely freed from these parasites after two doses.

The tobacco treatment, disinfection of yards, method of handling brooder chicks, and other precautions are described.

RURAL ENGINEERING.

State rivers and water supply commission, ninth annual report 1913-14 (Victoria Rivers and Water Supply Com. Ann. Rpt., 9 (1914), pp. 40, figs. 2).—This reports the activities and expenditures of the commission for 1913-14, on irrigation works especially.

Report of the Water Rights Branch, Department of Lands, for the year ended December 31, 1915, W. Young (Rpt. Water Rights Branch Dept. Lands, Brit. Columbia, 1915, pp. F 56, figs. 8).—This report for 1915 embodies a brief analysis of the work of the branch, including matters touched on in the report for the preceding year. The report of the board of investigation is also included.

Accounting and business procedure as applied to the construction of large irrigation projects, C. E. Bee (Engin. and Contract., 45 (1916), No. 12, pp. 269-274, figs. 25).—This article "gives a more or less complete description of the general business procedure, with the accompanying forms, suitable to the accounting of a large irrigation or hydro-electric project. All forms and reasonings are the result or outgrowth of experience. The general plan outlined is that now in use by the U. S. Reclamation Service on construction work."

Ochoco project and Crooked River investigations, J. T. WHISTLER and J. H. Lewis (Oreg. Cooper. Work, Dept. Int. U. S. Reclamation Serv., 1915, June, pp. 98, pls. 29).—This report, prepared in cooperation with the State of Oregon, deals with the irrigation and water power possibilities of Crooked River basin and its relation to the lower Deschutes River power development. The features to which this report has special reference are as follows:

- "(1) The Ochoco project, which will provide irrigation for 15,500 acres in the vicinity of Prineville, by storage of 40,000 acre-feet in a proposed reservoir on Ochoco Creek, 6 miles above Prineville, the spillway for which will be 113 feet above low water. The estimated cost of this project is \$51.30 per acre.
- "(2) The irrigation of part of the north unit lands of the Deschutes project by storage on Crooked River at the Post Reservoir site. Several alternative plans are considered, comprising a low-line development to irrigate 46,000 acres near Haystack Butte, and 9,000 across near Prineville, with 50 miles of main canal, and water by storage through the construction of a 131-ft. dam above Post at a cost of \$78 per acre; a high-line development for Haystack Butte lands, and all of Ochoco project lands at a cost of \$83 per acre.
- "(3) A study of the availability of Crooked River storage for increasing the minimum flow of lower Deschutes River for various hydro-electric power developments proposed in U. S. Geological Survey Water-Supply Paper 344 (E. S. R., 32, p. 279). A fall of 200 to 300 ft. in lower Deschutes River must be developed before Crooked River storage at its estimated cost becomes feasible for this purpose. . . .

"A duty for water of 1.85 acre-feet per acre of irrigable land is considered reasonable for the Ochoco project on the assumption that at least one-third of the project will be in grains. . . . It is estimated that the mean run-off from Ochoco Creek is about 48,000 acre-feet, with an extreme maximum and minimum of approximately 84,000 and 22,000 acre-feet during the past 12 years. . . . Soil and agricultural surveys of irrigable lands show the soils to be from 2 to 4 ft. or more in depth, with the physical character for irrigation and cultivation good. The plant food content of the bench lands is fair and for the bottom lands excellent. . . . It is estimated that during the period 1907 to 1915, inclusive, the mean annual run-off of Crooked River at Post was approximately 216,000 acre-feet, with a maximum of nearly 350,000 acre-feet and a minimum of 125,000 acre-feet."

Irrigation pumping by electric power, G. D. Longmur (Jour. Electricity, 36 (1916), No. 14, pp. 259-261).—This is a record of electric irrigation pumping in the Columbia River Valley giving comparative costs from representative plants picked at random from 110 plants with a concentrated load of over 700 horsepower. It is shown "that the plants operating as one unit secured a total of 33 in. of water for 70 acres at a total cost of \$7.35 per acre against the individual operations of 35 in. per acre at a total combined cost of \$11.30."

Electric irrigation pumping in Idaho, W. T. WALLACE (Jour. Electricity, 36 (1916), Nos. 12, pp. 227-230; 13, pp. 241-243).—After tracing the recent increase in irrigation pumping, the author reviews the results of recent surveys conducted by power companies, wherein it was found that plant efficiency rather than power rates was the most important factor in power costs.

Test made of model weir, B. D. Moses (Engin. Rec., 73 (1916), No. 15, p. 487, figs. 4).—Laboratory investigations made at the University of California on a model reduced 7:1 of the so-called Dolgeville model weir calibrated at Cornell University and described in Water Supply Paper 200 of the U. S. Geological Survey (E. S. R., 19, p. 385) are reported.

It was found that above heads of 1.4 ft. on the Cornell model (0.2 ft. on the California model) the curves for the coefficient c were of the same general type, and that the coefficient for the smaller weir was greater than that for the larger. The results of this and further comparisons are thought to furnish encouragement as to the reliability of deductions from small-sized weirs.

Durability of concrete draintile, O. B. WINTER and H. H. MUSSELMAN (Michigan Sta. Spec. Bul. 75 (1915), pp. 3-13, flgs. 4).—Field and laboratory tests of concrete tile are reported.

When apparently sound tile were so placed for four months as to be exposed to the action of the elements, to the action of water in a river bed to determine the effect a large amount of water coming in contact with the surface, and to the action of sewage by placing them in the discharge waters at a sewer outlet, no effect of the exposures was observed. When porous tile were placed in soil and water caused to percolate through their walls no disintegration was observed, but analyses of the water showed that some of the cement had been dissolved.

To show the effect of soil water upon the cement in concrete tile porous cups were prepared from pure quartz sand and cement and different solutions caused to pass through their structure. The results obtained are taken to indicate that "any solution percolating through concrete tile will dissolve some of the cement; in other words, some of the material which is necessary to maintain the tile structure intact, and point conclusively to the necessity for an impervious tile wall structure. Experiments also showed that solutions would percolate through incompletely hardened tile much more rapidly than through tile that had been properly and completely hardened; so the action of solutions upon partially hardened concrete tile is greater than upon those which have been properly hardened. . . . Conclusions reached from these preliminary experiments seem to point to the following as the most important factors for consideration in manufacturing concrete tile to fulfill desired requirements:

"(1) A Portland cement, meeting the requirements of the standard specifications for Portland cement of the American Society for Testing Materials, as revised to date. (2) Clean and preferably siliceous sand, graded in size from the finer particles to those which will just pass a 4-in, mesh screen, for all tile 10 in, and less in diameter. (3) Proper and accurate proportioning of the cement and sand. The method of measuring materials should be one which will insure separate and uniform proportions of each of the materials at all (4) Thorough mixing of materials, preferably by a power-operated batch mixer, and continuing for at least one minute after all materials, including water, are in the mixer. (5) Using a machine that accomplishes thorough packing of materials at proper consistency. (6) All other conditions of manufacture having been as outlined, hardening in a properly equipped and operated steam room will produce tile of the highest grade. When, however, hardening by water vapor is not possible, tile must be kept constantly wet on the surface by sprinkling with water for not less than seven days under favorable weather conditions, and longer during cold weather."

Details of these factors are discussed together with samples of concrete tile received which had failed.

Ground water in the Hartford, Stamford, Salisbury, Willimantic, and Saybrook areas, Connecticut, H. E. Gregory and A. J. Ellis (U. S. Geol. Survey, Water-Supply Paper 374 (1916), pp. 150, pls. 13, figs. 10).—This is a report on the origin, occurrence, distribution, and quality of the ground waters of five typical areas in Connecticut, with reference to their use for irrigation, farm domestic water supplies, and municipal water supplies.

Surface water supply of Ohio River basin, 1914 (U. S. Geol. Survey, Water-Supply Paper 383 (1916), pp. 125+XXXII, pls. 2).—This report, prepared in cooperation with the States of West Virginia and Illinois, presents the results of measurements of flow made on streams in the Ohio River basin during 1914.

The underground and surface water supplies of Wisconsin, S. Weidman and A. R. Schultz (Wis. Geol. and Nat. Hist. Survey Bul. 35 (1915), Econ. Ser. 17, pp. XXII+664, pls. 5, figs. 72).—This report, prepared in cooperation with the U. S. Geological Survey, deals with the general conditions affecting Wis-

consin water supplies and their chemical quality and describes local water supplies by counties. The first part covers the geography and geology, conditions controlling underground and artesian water, the flowing artesian wells of Wisconsin, prospecting for flowing wells, springs, and mineral waters, the general composition and uses of water supplies, chemical quality and factors affecting the mineralization of underground water supplies, and surface water supplies and their chemical quality.

Bacteria in commercial bottled waters, Maud M. Obst (U. S. Dept. Agr. Bul. 369 (1916), pp. 13).—Bacteriological examinations of bottled waters from 110 domestic springs are reported and discussed.

From the results obtained it is concluded that "bottled water for table use should either be actually sterile or should comply with a strict standard as to the number of *Bacillus coli* tolerated. No water should be permitted to be sold which is contaminated at the source in any manner. Inspection of springs and bottling establishments, together with the analysis of official samples, indicates that ignorance of proper precautions, carelessness, and neglect are fully as large factors in the contaminations found as are impurities actually present in the springs.

"The numbers of *B. coli* in official samples collected in the market may be safely assumed to be less rather than greater than the numbers in the freshly bottled stock. The data . . . show the need of improvement in the bacteriological condition of many of the brands of bottled water to be found in the market. Careful consideration of cases to which special study has been given shows that there are some springs used for the production of commercial bottled waters which should not be so used. It is evident that the presence of serious and unremovable contamination should shut the water of a spring permanently from the market. . . .

"The results clearly show that bottled waters can be made to conform to the requirements of the U. S. Public Health Service for drinking water furnished upon trains; that is, that not more than one 10-cc. sample out of five should show the presence of *B. coli.*"

Study of the purification of water by aluminum sulphate, A. A. Bado and V. J. Bernaola (Bol. Obras Púb. Argentina, 12 (1915), No. 4-6, pp. 185-212, pls. 4).—Experiments on the purification of the La Plata River water with aluminum sulphate led to the conclusion that the formula A=2 (p=5) for determining the quantity of aluminum sulphate necessary for the purification of river water gives results which are unnecessarily high. In this formula A=the necessary quantity in milligrams of aluminum sulphate and p=the milligrams of calcium carbonate in the water. It is further concluded that owing to the complexity of the factors affecting the action of the coagulant it is impossible to determine exactly the quantity of aluminum sulphate necessary for thorough purification. The necessary quantity of aluminum sulphate is considered to depend on the alkalinity of the water, the organic matter content, and the matter in suspension. It is also concluded that the precipitated aluminum hydrate adsorbs organic matter in solution.

The filtering action of soil on water containing colloids, K. Sack (Gsndhts. Ingen., 38 (1915), Nos. 46, pp. 525-528; 47, pp. 538-543, fig. 1; 48, pp. 549-555).—Studies on the colloidal content of samples of several types of sewage and colloid-holding waters, including domestic and industrial sewage and sewage from septic and settling tanks, and experiments on the filtering and purifying action of a crystalline powder composed of the important constituents of agricultural soil, and of moor and humus soil containing much organic matter, heavy and weak loam soils, and light sand soil, are reported. The method of Marc for colloid determination was used.

The sewage of small cities was found to contain the maximum amount of colloids about noon, while purely domestic sewage contained more colloids in the morning. The colloid content comprised from one-third to one-half of the total organic content. An exchange of organic sewage colloids with inorganic colloids of the filtering material was established. It was found that the soils were able to adsorb considerably weaker colloids than the crystalline powder. Colloid adsorption by soils was effected not only by their crystalline constituents but also by their amorphus constituents. By washing out the soils with water the salts were first removed and then the colloids. The greatest part of the soil colloids was found to be of an inorganic nature, even in the moor and humus soils.

The soils adsorbed organic colloids before inorganic colloids and exchanged inorganic soil colloids for the organic putrefactive sewage colloids, so that considerably more organic colloids were fixed by the soil than their theoretical adsorptive powers indicated. Freezing and drying of soils strongly increased their peptonizing powers, especially soils rich in humus.

The colloids fixed on the surfaces of soil particles in their turn adsorbed molecularly dissolved substances whereby a more extensive power of adsorption of the soil for colloids was reached.

These results are taken to indicate that the colloid adsorbing properties of soils are the primary factors in the purification of sewage by soils, and that they act in connection with the secondary purification processes involving catalytic and bacteriological influences through the agencies of which adsorbed organic colloids are decomposed and mineralized. Further experiments along this line are in progress.

Stream pollution and sewage disposal in Illinois with reference to public policy and legislation, L. K. Sherman (Ill. Rivers and Lakes Com. Bul. 16 (1915), pp. 30).—This report deals with stream pollution and sewage treatment and reviews the laws governing stream pollution of Illinois and other States.

Second annual report of the engineer of the Oregon State Highway Commission for the year ended November 30, 1915, E. I. CANTINE (Ann. Rpt. Engin. Oreg. Highway Com., 2 (1915), pp. 90, pl. 1, figs. 16).—This reports highway construction and expenditures in Oregon for the year ended November 30, 1915, as conducted by the engineer of the state highway commission.

Road maintenance in the several States (Municipal Jour., 40 (1916), No. 14, pp. 465-479, figs. 3).—The reports of 20 state highway commissioners, engineers, or other officials are given, describing the methods most successfully employed by each in maintaining the roads of his State, together with a statement of opinion concerning the importance of road maintenance.

Maintenance of Indiana highways, G. E. Martin (Purdue Univ., Dept. Engin., Highway Bul. 1 (1915), No. 1, pp. 24, figs. 10).—The purpose of this bulletin is to present the best current practice in road maintenance operations, with special reference to the roads of Indiana. It is stated that part of the material was drawn from publications of the Office of Public Roads of the U. S. Department of Agriculture.

Economics of highway engineering, L. I. Hewes (Cornell Civ. Engin., 24 (1916), No. 6, pp. 237-246).—The author discusses road administration, finance, cost, traffic, and cost comparison for different types of surfaces, with reference to their bearing on highway engineering economy.

Construction field books for bituminous macadam highways, J. T. Crawford (Good Roads, 49 (1916), No. 14, pp. 164-166, figs. 4).—Construction field books, the objects of which are to show the highway as planned, staked, and constructed, are described and illustrated, including a grade book, culvert book, stone course book, and a bituminous material book. A book for the engineer

in charge contains summaries of all items entering into the construction of the highway.

What the highway engineer should know about bituminous materials, P. Hubbard (Cornell Civ. Engin., 24 (1916), No. 6, pp. 260-278).—In outlining in a general way what the highway engineer should know about bituminous materials, the author deals with the classification of bituminous materials, refining processes, petroleums, asphalts, tars, physical and chemical tests of bituminous road and paving materials, and specifications.

Road and concrete materials, H. S. Mattimore (Cornell Civ. Engin., 24 (1916), No. 6, pp. 280–293, figs. 3).—This article deals with methods of stone, gravel, and slag testing; discusses the proportioning and inspection of concrete materials; and gives tables of tests of limestone, dolomite, sandstone, quartzite, syenite, and trap from different parts of the State of New York. The results of compression tests of sand mortars and diagrams showing the effect of fine sand in concrete, the effect of tamping and moisture content on void determination in sand, and the importance of screening sand are also given.

Revised practice on road building (Cement Era, 14 (1916), No. 3, pp. 60-61).—The principles adopted by the Second National Conference on Concrete Road Building as representing good practice in the construction of concrete roads and pavements are given. These include sections on materials, drainage, grading, subgrade, forms, pavement section, joints, mixing and placing concrete, retempering, protection and curing, opening to traffic, one-course pavement, and integral curb.

Useful feet-miles conversion table for highway engineers (*Engin. Rec.*, 73 (1916), No. 15, p. 482).—A table of figures computed for Connecticut state highway work is given.

An unusual application of the rattler test for paving bricks, F. L. Roman (Engin. and Contract., 45 (1916), No. 14, p. 329, figs. 2).—Rattler tests of partly worn paving brick blocks, using angular and spherical shots, showed abnormally high losses not only in percentage but in actual weight. "It appeared, therefore, that the blocks had a fairly hard exterior but a rather soft interior."

Drainage and preparation of subgrades, J. H. Huber (Cornell Civ. Engin., 24 (1916), No. 6, pp. 247-254).—The author reviews highway drainage in general, taking up more especially underdrainage, foundation courses, culverts, and preparation of subgrades. "In the design of the drainage system of any highway, it is necessary that a survey be made by walking over it on foot and all drainage conditions noted. The best time to do this is at the time of the spring run-off and after the new grade line has been approximately fixed."

Reinforced-concrete construction.—III, Bridges and culverts, G. A. Hool and F. C. Thiessen (New York and London: McGraw-Hill Book Co., 1916, vol. 3, pp. XXII+688, pls. 7, figs. 569).—This is volume 3 of this series (E. S. R., 31, p. 186) and deals with bridges and culverts. It is divided into eight parts.

Part 1, on arch bridges, contains the following chapters: General data, deflection of curved beams, analysis of the symmetrical arch by the elastic theory, design of an earth-filled arch bridge, use of influence lines in arch analysis, unsymmetrical arches, arches with elastic piers, arch analysis by the method of the ellipse of elasticity, details of arch bridges, construction of arch bridges, three-hinged arches, and patents. Part 2, on slab and girder bridges, contains chapters on slab bridges, simple girder bridges, continuous girder bridges, cantilever bridges, and reinforced concrete in steel bridge construction. Part 3, on culverts, deals with factors in culvert design, pipe culverts, box culverts, and arch culverts. Part 4, by A. W. Ransome, contains notes on the construction plant;

part 5, by L. H. Allen, contains notes on estimating; part 6, by W. J. Titus, deals with the artistic design of concrete bridges; part 7, by A. M. Wolf, deals with the construction in detail of several types of concrete bridges; and part 8, by P. Aylett and P. J. Markmann, deals with European concrete bridges.

How the Forest Service bridges the more remote stream crossings (*Engin. Rec.*, 73 (1916), No. 15, pp. 485, 486, figs. 4).—Methods of difficult but inexpensive construction as adopted by the Forest Service of the U. S. Department of Agriculture in bridging mountain streams of the Northwest are briefly described and illustrated.

Keeping the engine in good running order, C. V. Hull (Gas Power, 13 (1916), No. 9, pp. 30, 32, 64, 66).—Suggestions are given on the care of the valve system and the timing of valves on farm gas engines.

[Repair of gas engines], J. F. Hobart (Gas Power, 13 (1916), No. 9, pp. 54, 56, 58, fig. 1).—Information on the proper use of set screws is given.

Directory and specifications of gasoline and oil farm tractors (Farm Machinery, No. 1277 (1916), pp. 18-20, 25).—This directory contains specifications for 176 tractors of 98 different makes.

Directory and specifications of plows for tractor use (Farm Machinery, No. 1277 (1916), pp. 26, 27).—This directory contains specifications for 82 plows of 18 different makes.

The development and efficient utilization of animal, steam, electric, and internal-combustion motor plows, A. Wolff (Beiträge zur Entwicklung und wirtschaftlichen Verwendbarkeit von Gespann-, Dampf-, Elektro- und Explosions- motorpfügen. Inaug. Diss., Univ. Giessen, 1913, pp. VIII+96).—This report deals with the development of horse-drawn plows, steam, electrical, and motor plows, the extent to which the use of each is justified on the basis of efficiency, the relation of the cost of mechanical to animal work, and of the cost of motor to steam plowing. It is pointed out that in Germany deep plowing may be more cheaply done with mechanical than with animal power; that in such work the mechanical power works a great saving in expensive animal power, and that more actual work is accomplished per unit of time.

How to plow a field with a tractor, R. Olney (Gas Power, 13 (1916), No. 9, pp. 10, 12, figs. 3).—This is an illustrated description of what is considered the best method of laying out a field for plowing with a tractor.

Lighting farm buildings, J. L. Mowry (*Univ. Minn., Dept. Agr., Ext. Bul.* 58 (1915), pp. 8, figs. 7).—This pamphlet describes and diagrammatically illustrates small oil, acetylene gas, and electric lighting systems for farm buildings.

A simple ice precooling plant, MARY E. PENNINGTON (*Proc. Amer. Warehousemen's Assoc.*, 25 (1915), pp. 266-272, fig. 1).—A simple ice precooling plant designed and tested by the Bureau of Chemistry of the U. S. Department of Agriculture is described and illustrated.

"The experimental box . . . is 22 ft. 2 in. long by 11 ft. 4 in. wide by 8 ft. 10 in. high. The bunker occupies 3 ft. 8 in., leaving the box 7 ft. 6 in. wide in the clear. The wire basket holding the ice is 30 in. wide, inside measurement. The cost of such a box is approximately \$800. The interior of the box was painted and enameled to insure as dry an atmosphere as possible."

Test records are also given.

RURAL ECONOMICS.

Psychic causes of rural migration, E. R. Groves (Amer. Jour. Sociol., 21 (1916), No. 5, pp. 623-627).—The author states that "the city furnishes forceful, varied and artificial stimuli; the country affords an environment of stimuli in comparison less strong and more uniform. Minds that crave external, quan-

titative stimuli for pleasing experiences are naturally attracted by the city and repelled by the monotony of the country. On the other hand, those who find their supreme mental satisfactions in their interpretation or appreciation of the significant expression of the beauty and lawfulness of nature discover what may be called an environment of qualitative stimulations. The city appeals, therefore, to those who with passive attitude need quantitative, external experiences; the country is a splendid opportunity for those who are fitted to create their mental satisfactions from the active working over of stimuli that appear commonplace to the uninterpreting mind."

Suggestion and city drift, E. R. GROVES (Rural Manhood, 7 (1916), No. 2, pp. 47-52).—In this article are discussed the psychic suggestions received by boys and girls on farms from their parents, in school, and from the city itself, that tend to draw the young men and women from the rural districts into the cities and towns.

Government aid and direction in land settlement, E. Mead (Fort Collins: Colo. Agr. Col. Ext. Serv., 1916. pp. 14).—In this address, delivered at the 1916 session of the Colorado Farmers' Congress, the author describes the methods used in obtaining credit for land settlers in Australia and its adaptability to conditions found in the Western States.

Russian land reform, R. T. Ely (Amer. Econ. Rev., 6 (1916), No. 1, pp. 61-68).—This article consists of a brief description of the significance of the Russian land reform movement and comments by various authors regarding this movement.

A system of rural credits adapted to federal reclamation projects, F. H. Sears (Fallon, Nev.: Author [1916], pp. 31).—This pamphlet contains a brief description of the Water Users' Associations connected with reclamation projects, and of methods that may be used to adapt the Landschaft and Credit Foncier systems to the needs of farmers on these projects. It is pointed out that some system of credit is needed if the reclamation farmers are to be successful, and that the success of our reclamation work depends upon the success of the farmers.

Farmers' need for productive credits amply cared for by present facilities, P. W. Goebel (Econ. World, n. ser., 11 (1916), No. 15, pp. 466-469).—The author has outlined his scheme for providing credit for Kansas farmers, proposing the passage by the state legislature of an enabling act for the organization of one land bank with a capital stock of about \$1,000,000. The bank would be located at the state capitol, and confine its business to the making of loans on farms occupied and cultivated by the owners, either on straight payment or upon the amortization plan.

Management of sandy-land farms in northern Indiana and southern Michigan, J. A. Drake (U. S. Dept. Agr., Farmers' Bul. 716 (1916). pp. 29, figs. 3).—This deals with the problems involved in the improvement and management of farms on the sandy-land areas which occur in different parts of northern Indiana, southern Michigan, and in a part of northwestern Ohio. It outlines a plan whereby a man with limited means, by beginning with suitable cash crops, may build up one of these farms and at the same time derive some revenue from it, finally developing a well-balanced farm system.

The normal stages of development suggested for the average sandy-land farm are as follows: (1) Growing and selling cash crops, among which soy beans or cowpeas for seed should have a prominent place; (2) a transition stage, in which live stock should be introduced as rapidly as fences can be purchased and built, and as the farm can be made to produce the necessary feed and pasture; and (3) a general and well-diversified farm system, with the proper balance between cash crops and live stock which will afford profitable

employment for the entire year, maintain crop production in a reasonably high state and yield a suitable labor income.

Farm management for boll-weevil conditions, J. R. Fain (Ga. State Col. Agr. Bul. 98 (1915), pp. 15, figs. 4).—The author outlines two systems of management, one for diversified farming before the coming of the boll weevil, the other for a modification of the plan under boll-weevil conditions.

The farm first outlined is to consist of 200 acres, of which 50 are in pasture, 100 in a 3-year rotation of cotton, corn, and oats followed by cowpeas, and the remainder used for raising corn for silage, soy beans, and peanuts, grazing crops for hogs, a garden, and a small grass plat.

Under boll-weevil conditions, 8 of the 33\frac{1}{3} acres previously devoted to cotton remain in cotton, the remainder being used either for corn and velvet beans for cattle, peanuts and soy beans for hogs, Irish and sweet potatoes, or vetch and oats for hay. The remainder of the farm is to be operated as in the first instance.

The author has also outlined a plan for a smaller farm with the same system of management.

Terminal market problems, J. E. BOYLE (Reprint from Quart. Jour. Univ. N. Dak., 6 (1916), No. 2, pp. 159-167).—This pamphlet consists principally of excerpts from government documents regarding terminal elevators, produce exchanges, hedging and speculation, grading and dockage, and storing and mixing. A brief bibliography is appended.

Patronage dividends in cooperative grain companies, J. R. Humphrey and W. H. Kerr (U. S. Dept. Agr. Bul. 371 (1916), pp. 11).—The authors divide the cooperative grain companies into 5 classes: (1) Regularly incorporated companies; (2) single elevators organized under cooperative law; (3) the county unit plan, a number of elevators belonging to one cooperative association; (4) a similar plan but on a larger scale; and (5) similar to (4) but organized as separate county organizations to secure the benefits of trading on boards of trade.

The authors point out that the dividends may be distributed on the money value of the individual transactions or on the basis of the amount of grain contributed by the individual members.

Methods of handling patronage dividends under the various conditions mentioned above are outlined.

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 2 (1916), No. 5, pp. 41-48).—This number gives the usual monthly estimates of the farm value of the more important agricultural products, and the range of prices at important markets, with detailed statistics concerning the condition on May 1 of winter wheat, rye, hay, spring pasture, spring plowing, and spring planting.

Special reports are included on the strawberry acreage and the percentage of the total harvested each month, apiary conditions, maple sugar and sirup production and prices, the Texas Bermuda onion crop, prices of meat animals, stocks of hay on farms May 1, and yearly summaries of the world's production of important crops.

Statistics of the production of cereals and legumes (Estadistica de la Produccion de Cereales y Leguminosas. Madrid: Junta Consult. Agron., 1914, pp. 30; 1915, pp. 31).—These reports continue data previously noted (E. S. R., 30, p. 791).

Proceedings of the conference relative to the marketing of live stock, distribution of meats, and related matters (U. S. House Representatives, 64. Cong., 1. Sess., Doc. 855 (1916), pp. 152, fig. 1).—This conference, held at Chicago, November 15 and 16, 1915, under the auspices of the U. S. Department of Agriculture, was called with a view to ascertaining the essential facts and

conditions pertaining to the marketing of live stock, determining the feasibility of improving marketing methods and facilities, and promoting a better understanding among the various interests connected with the industry. The discussion covered the different phases of the production and distribution of live stock and live-stock products, beginning with the live-stock producers and ending with the retail trade.

Statistical information relating to stocks, cotton, grain, provisions, live stock, and seeds, 1915 (Chicago: Howard, Bartels & Co., 1915, pp. 54).—In this report are included Chicago's grain inspection rules and the daily movement and prices of agricultural products at Chicago for 1915, together with data showing by comparison the monthly movement for earlier years. Data are also given relative to the crops and trade in the principal foreign countries.

Resources of Nebraska (Nebr. Dept. Labor Bul. 31 [1916], pp. 167).—This report contains data showing the mortgages released and filed during the year, the surplus shipments of agricultural produce, and brief topographic notes as to soils by counties.

AGRICULTURAL EDUCATION.

Agricultural education, A. C. Monahan and C. H. Lane (*Rpts. Comr. Ed. U. S.*], 1914, I, pp. 291-318; 1915, I, pp. 295-316).—A review is given of the progress in agricultural education in 1913-14 and 1914-15 in the agricultural colleges and normal, secondary, and elementary schools in the United States, agricultural education at meetings of the year, educational work of the U. S. Department of Agriculture, and the principal developments of agricultural education in other countries.

Agricultural and mechanical colleges (*Rpt. Comr. Ed.* [*U. S.*], 1914, II, pp. 277-314).—This is a compilation from official sources of statistics of the land-grant colleges with reference to faculties, students, courses of study, value of funds and equipment, revenues, additions to equipment, etc., together with a summary of statistics for the years 1891-2 to 1913-14 and a summary of legislative acts and appropriations in 1914 in various States,

Home economics, Henrietta W. Calvin and Carrie A. Lyford (*Rpt. Comr. Ed. [U. S.], 1915, I, pp. 317–343*).—Following a review of the series of four bulletins on Education for the Home, by B. R. Andrews (E. S. R., 33, p. 397), the authors report on home-economics instruction in state colleges, universities, normal schools, summer schools, and public and rural schools, state supervision, state courses of study, textbooks for home economics teaching, use of apartments or houses in public-school teaching, cafeterias as practice places for home-economics teaching, rural-school luncheons and lessons in food preparation, continuation schools and home economics for adult women, home-economics education for colored students, laws affecting home-economics instruction, home-economics associations, and tendencies and developments in home economics.

Education for the home, B. R. Andrews (*Rpt. Comr. Ed.* [U. S.], 1914, I, pp. 319-344).—This report deals with the subject matter and method in education for the home, the status and program of education for the home, including fundamental principles and the various points in our school system and social organizations in which they find expression, and local progress in education for the home in elementary and high schools, practical household arts work in public schools, vocational classes, normal schools, and colleges.

Education for child nurture and home making outside of schools, Mrs. F. Schoff (Rpt. Comr. Ed. [U. S.], 1914, I, pp. 363-374).—This is a review of what is being done in the education for child nurture and home making by organizations interested in this work, and of home education extension work of high and normal schools and colleges.

A rural school experiment, S. S. RITTENBERG (Clemson Agr. Col. S. C., Ext. Div. [Pub.], 1916, Jan., pp. 24, pls. 3).—This is a report on the first year's work of a plan undertaken as an experiment in Darlington County, S. C., in September, 1914, for the purpose of giving agriculture in rural schools and solving the problem of the lack of competent teachers.

The agricultural instruction in five selected consolidated schools was placed in charge of J. N. Napier. Each school had three acres of land for field crop demonstrations and one acre for orchard work. The preliminary work, weekly program, classroom, field, club, and demonstration work, and the effects of the plan on the pupil, the parents, the educational conditions in the county, and the agriculture of the community at large are discussed.

During the first year the expenses were \$2,500, including the salary, cost of automobile, and traveling expenses of the teacher. This year three agricultural teachers are giving instruction in 14 schools and are receiving a total of \$5,700, including salaries of \$2,500, \$1,800, and \$1,400, respectively, and traveling expenses. At present nearly three-fifths of the total enrollment of boys from the sixth grade upward are being taught practical agriculture. There are new more than 700 boys attending the public schools of the county, and under this method it is thought that five teachers can instruct all these boys in practical agriculture at a cost not exceeding \$10,000 or \$12,000. If the experiment proves successful after a two-year trial it is planned to adopt it throughout the State,

Elementary agricultural instruction (*Agr. Gaz. Canada*, 3 (1916), *No.* 1, pp. 60-77, figs. 5).—This is a review and forecast of elementary agricultural instruction in the provinces of Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Manitoba, Saskatchewan, Alberta, and British Columbia.

Farm and home management schools and agricultural housekeeping schools (Ztschr. Landw. Kammer Schlesien, 19 (1915), Nos. 47, pp. 1245, 1246; 50, pp. 1317, 1318, fig. 1; 51, pp. 1342-1344, fig. 1).—An account is given of the aim and instruction of farm and home management schools and of agricultural housekeeping schools. The former are intended for the daughters of large farm owners and for the training of teachers of home economics for agricultural housekeeping schools and itinerant cookery schools, while the latter are for the daughters of medium and small farmers. Applicants for admission to the former, especially to the seminar courses, must have completed at least a ten-year course at a higher girls' school or must take a special entrance examination, while the completion of the common school is sufficient for admission to the housekeeping schools.

Report of the department of agriculture of Sweden, 1913 (K. Lantbr. Styr. [Sweden] Underdåniga Ber. 1913, pp. [10]+648, figs. 2).—This report contains the usual accounts of the various agencies for the promotion of Swedish agriculture, including the work of agricultural, horticultural, dairy, and house-keeping schools and dairy, chemical, and seed-control stations.

Women's work in agriculture in peace and war (Jour. Bd. Agr. [London], 22 (1915), No. 9, pp. 859-866).—A review is given of the report of the Agricultural Education Conference on Agricultural Education for Women and of a circular letter to the secretaries of the county war agricultural committees on the employment and training of women, followed by an account of the experience of some farmers who have recently engaged women to take the place of men who have enlisted.

The Agricultural Education Conference finds that (1) the instruction available in England for women consists of courses in men's institutions which admit women students, and additional short courses or classes for women

which are attached to institutions for men; (2) that the amount of instruction offered to rural women, or young women of the tenant farmer or small-holder class, consisting of itinerant instruction and in a few counties of short courses at a farm school or similar institution, is totally inadequate. Only two of the twelve institutions which may be classed as farm schools attempt to give any practical instruction except in dairying. In the opinion of the conference the itinerant instruction should take the form of organized classes rather than lectures, especially in poultry keeping and horticulture.

The conference recommends that (1) the curriculum provided for girls should include instruction in the care of animals, the minor farm processes, and domestic economy, including fruit bottling and jam making; (2) instruction in home management should be provided for women in any grouped course of agricultural education, as in Ireland, Belgium, and Canada, where instruction in home management forms the central feature of the agricultural education provided for women; and (3) there is room for the provision, at one or more of the collegiate institutions, whether entirely devoted to women or not, of a systematic course in general agriculture comprising both the practical and scientific side, for women of the professional and land-owning classes and the daughters of the larger farmers, whether they intend to become teachers or to take positions involving management.

[Animal husbandry extension course for boys' and girls' clubs], C. A. Norcoss (Agr. Ext., Univ. Nev. Buls., 1916, Nos. 1, pp. 20, figs. 10; 3, pp. 20, figs. 14).—These bulletins comprise the first six lessons of the course and deal with the three general divisions of cattle, viz, dairy, dual-purpose, and beef cattle, including a study of the origin of cattle, the development by breeding of the three distinct types, history and characteristics of the leading breeds of each, farm and range management, and judging cattle.

Arithmetic problems based upon agricultural club work (N. C. Agr. Ext. Serv. Circ. 8 (1916), pp. 10-15).—This is a series of 50 problems in arithmetic, based on corn, pig, and poultry club work and prepared for supplementary work in rural schools.

MISCELLANEOUS.

Twenty-eighth Annual Report of Louisiana Stations, 1915, W. R. Dodson (Louisiana Stas. Rpt. 1915, pp. 32).—This contains the organization list, a report by the director discussing the work of the stations, an account of their progress including brief departmental reports, and a financial statement as to the federal funds for the fiscal year ended June 30, 1915, and as to the state funds for the fiscal year ended November 30, 1915. The experimental work reported is for the most part abstracted elsewhere in this issue.

Twenty-third Annual Report of Minnesota Station, 1915 (Minnesota Sta. Rpt. 1915, pp. 74).—This contains the organization list, a financial statement for the federal funds for the fiscal year ended June 30, 1915, and for the state funds for the fiscal year ended July 31, 1915, and a report of the director summarizing the work of the station and its substations. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 2, pp. 15, figs. 12).—This number contains brief articles on the following subjects: The Root Maggot Pest, by E. B. Stookey; Plant Good Potato Seed, by J. L. Stahl; Field Corn in Western Washington, by E. B. Stookey (see p. 339); Teaching the Young Stock to Roost, by Mr. and Mrs. G. R. Shoup (see p. 377); and Preserving Eggs, by W. R. McBride.

NOTES.

Alabama College.—A state appropriation of \$100 per annum for the years 1915 to 1918, inclusive, is now available for each county that raises a similar sum to be used for prizes, premiums, and other phases of boys' and girls' club work. These funds are spent under the joint supervision of the state board of agriculture and the county authorities, under plans and rules submitted by the professor of school agriculture of the college. The club work for boys in each county is also under the general supervision of the county farm demonstration agent and that for girls under the supervision of the county canning club agent.

Alaska Stations.—C. C. Georgeson, agronomist in charge, received the degree of D. Sc. from his Alma Mater, the Michigan College, at its recent commencement.

Delaware College.—Gifts have been made to the college from an unannounced donor during the past year amounting to \$1,000,000, and are being utilized largely for buildings. In addition to those previously noted, Wolf Hall, named in honor of Dr. Theodore R. Wolf, who for over a quarter of a century was professor of chemistry, is now in course of construction. This building is intended primarily to house all the activities of the agricultural department, but for a time will also furnish quarters for general chemistry and biology. It will cost, partially equipped, \$280,000. A new dormitory for men will also be started shortly to accommodate about 75 students.

Florida University and Station.—Dr. J. E. Turlington, superintendent of the Craven County Farm Life School, of Vanceboro, N. C., has been appointed professor of agronomy, vice W. C. Etheridge resigned to become professor of farm crops in the University of Missouri. John Belling, assistant horticulturist and editor of the station, resigned July 1.

Georgia College.—A cooperative arrangement has been made with the Office of Public Roads and Rural Engineering of this Department, whereby J. V. Phillips of that Office will be given headquarters at the college. M. D. Wood has been appointed instructor in animal husbandry and Dr. J. E. Severin, instructor in veterinary medicine.

Hawaii Federal Station.—C. W. Carpenter, of the Office of Cotton and Truck Disease Investigations of this Department, was transferred June 1 to the position of plant pathologist in charge of the new division of plant pathology.

Kentucky University.—Beginning with the new academic year, a one-year course in practical agriculture is to be offered. No entrance examinations are to be required or restrictions made as to age.

The boys' pig club work, begun in 1915, has now been extended to 40 counties with a membership of 1,250. Bankers, business men, and farmers have cooperated in the enterprise by distributing over \$5,000 worth of pure-bred pigs among the members.

Massachusetts College and Station.—A special commission, consisting of the state supervisor of administration, the state commissioner of education, and

three additional members selected by the Governor, was authorized by the last legislature to investigate the general subject of agricultural education at the college and the development of the agricultural resources of the Commonwealth. This commission was directed to study and report before January 10, 1917, on the policy of the college, its use of the funds at its disposal, the advisability of further expenditures for buildings, lands, etc., the relation of the college to other agricultural institutions in the State, and similar questions. An appropriation of \$7,500 was made for holding hearings and other expenses. Governor McCall has subsequently announced as his appointments to the commission, Dr. L. Clark Seelye, ex-president of Smith College, William F. Whiting, a paper manufacturer of Holyoke, and Warren C. Jewett, for many years secretary of the State Grange.

The department of botany has been reorganized with A. V. Osmun in charge. Beginning September 1, Orton L. Clark, assistant plant physiologist, will devote part time to instruction work, and Dr. P. J. Anderson, associate professor of botany, will give part time to the station as associate plant pathologist

W. A. Allen and T. L. Harrocks have been appointed assistant chemists, the former in the fertilizer section and the latter in the feed and dairy sections. C. L. Beals has been assigned to chemical work in nutrition. George L. Farley, superintendent of schools in Brockton, has been appointed supervisor of junior extension work, this dealing with the boys' and girls' clubs and similar activities.

Mississippi College and Station.—W. C. Trotter, of Winona, and J. S. Howerton, of Baldwyn, have succeeded E. M. Clark and T. W. Carter, as members of the board of trustees.

Minnesota University and Station.—R. W. Thatcher has been appointed assistant director of the station.

The division of agricultural chemistry has been reorganized as the division of agricultural biochemistry, and will provide for instruction and research in plant chemistry, biochemistry, cereal technology, and methods of agricultural chemical analysis. Dr. R. A. Gortner has been appointed associate professor of biochemical research and associate agricultural biochemist of the station, and George E. Holm research assistant in agricultural biochemistry.

The work relating to animal production has been organized into an animal industry group, which includes the divisions of animal husbandry, dairy husbandry, poultry husbandry, animal nutrition, and veterinary science. Dr. C. W. Gay, professor of animal husbandry in the veterinary college of the University of Pennsylvania, has been appointed professor of animal husbandry and animal husbandman, and will be chairman of the group and of the animal husbandry division. H. H. Kildee, professor of animal husbandry and assistant chief of dairy husbandry in the Iowa College and Station, has been appointed professor of dairy stock and production and chairman of the dairy husbandry division.

Missouri University and Station.—Hereafter all dairy products used by the university are to be purchased or manufactured by the department of dairy husbandry. This policy is adopted to insure pure dairy products for use in the various university dormitories and incidentally makes it possible for more complete instruction to be given by the department.

The Iowa College conferred the honorary degree of D. Sc. on C. H. Eckles at its last commencement.

The resignations have been accepted of C. B. Hutchison as professor of farm crops, J. G. Watson as extension assistant professor of dairy husbandry, M. A. R. Kelley as instructor in agricultural engineering, and B. E. Sive as assistant in agricultural chemistry. Recent appointments include E. W. Lehmann, assistant professor of agricultural engineering at the Iowa College, as associate professor

of agricultural engineering; A. C. Ragsdale, instructor in dairy husbandry at the West Virginia University, as extension assistant professor of dairy husbandry; W. A. Albrecht as instructor in soils; R. A. Kinnaird, instructor in agriculture at the Maryville State Normal School, as extension instructor in soils; H. G. Newman as assistant in veterinary science; P. H. Ross, county agricultural agent of Leavenworth County, Kans., as county agent leader; Harry T. Bennett as assistant in agricultural chemistry; Dr. E. H. Bullock as assistant in the agricultural extension service; and J. H. H. Mote as district agricultural agent in the Ozark region.

Montana College and Station.—Resignations are noted of G. E. Smith as assistant chemist, effective August 1, and D. C. Wood, as assistant professor and assistant in farm management, effective September 1, the latter to accept a position as extension professor of farm management in the University of Missouri

Nebraska University and Station.—The erection of the agricultural engineering building has been postponed on account of the present high cost of construction. Bids for erecting this building have twice been advertised for and refused. It is probable that another effort will be made to secure bids about March, 1917.

Frank C. Dean has resigned as agricultural editor to accept a similar position in the Ohio State University, effective September 1.

Nevada Station.—The collection has been begun of certain lupines poisonous to live stock for the purpose of extracting the poisonous principle and studying its chemical nature. A new line of work planned is a study of methods of avoiding the heavy losses now experienced in bringing sheep through the period of spring starvation when they are coming from the winter ranges of the southern deserts to the lambing grounds in the northern portion of the State.

Rutgers College.—Alva Agee, director of the division of extension in agriculture and home economics and professor of soil fertility, has been appointed secretary of the new state board of agriculture. John H. Hankinson has been appointed state leader in farm demonstrations and Alexis L. Clark has resigned as assistant state leader.

Cornell University and Station.—The state fiscal year has been changed to end June 30 instead of September 30 so that it now coincides with that of the Federal Government. This is proving to be of great convenience to the college of agriculture, particularly in the administration of its projects under the Smith-Lever Act.

A. R. Mann, formerly secretary of the college of agriculture, has been appointed acting dean and director beginning August 1.

The summer session of the forestry school was attended by about 30 seniors and graduate students as compared with about 20 the previous year. The program included practical woods work in the neighborhood of Lake Saratoga, where because of the nearness of fairly large centers of population there is a close utilization of forest products and a type of lumbering different from that studied in the Adirondacks in 1915. G. H. Collingwood has been appointed extension professor of forestry, vice R. D. Moody resigned to become a member of the Wisconsin conservation commission.

Clinton DeWitt Smith, instructor in extension teaching and widely known as an educator in both North and South America, died at Buffalo, N. Y., August 5, while on a lecture tour for the college of agriculture. Professor Smith was born at Trumansburg, March 7, 1854, was graduated from the university in 1873, and taught in the Star Military Institute and practiced law for brief periods. He became assistant agriculturist in the station in 1890, director of the Arkansas Station in 1891, and director of the Minnesota Station and professor of dairy

husbandry from 1891–1893. In the latter year he went to the Michigan College as professor of agriculture, continuing in this position until 1899. In 1895 he was also made director of the Michigan Station, and in 1899, dean of the department of special courses and superintendent of farmers' institutes. In 1908 he accepted the presidency of the Louis Queiros School of Agriculture of Sao Paulo. Brazil, returning to this country after a five-year period of service in 1913. His subsequent life was spent on his farm at Trumansburg and in the extension service of the college of agriculture.

New York State Station.—John C. Baker, Ph. D. (Columbia, 1916), has been appointed associate chemist. William W. Baer has been appointed assistant chemist for work in the agronomy department, succeeding E. J. Lewis resigned to engage in commercial work.

Ohio Station.—Recent appointments include Wayne Van Pelt as assistant in botany, W. C. Gangloff as assistant in chemistry, and H. J. Conlin as assistant in soils. C. E. Mangels, assistant in agricultural chemistry at the Missouri University and Station, has been appointed assistant in nutrition beginning September 1, succeeding Chas. M. Fritz resigned.

Oregon College and Station.—Farmers' days have recently been held at the Moro dry-farming substation and the Eastern Oregon substation near Union. The institutions were opened to inspection and the leading experimental work was explained to hundreds of farmers.

A West-side Farmers' Week was conducted by the college extension service at McMinnville, July 3 to 8, with more than 1,000 farmers and their wives in attendance.

Gilbert B. Posey, research assistant in botany, has been appointed scientific assistant in forest pathology in this Department.

Porto Rico Insular Station.—During the past year experimental plantings have been made of pineapples, vegetables, grapefruit, and other economic plants. About 300 tons of seed cane were distributed and the station has about 1,000 seedlings under test. Excellent results are reported by planters with D-117 and B-208.

Work with citrus diseases, analyses of tropical fruits, and a citrus survey are being begun. About 8,700 packages of plants, 5,000 of fruits, and 1,000 of seed were inspected under the plant quarantine. An appropriation of \$1,000 was made by the Porto Rican legislature for the construction of a plant house.

George N. Wolcott has resigned as assistant entomologist to complete Ph. D. work at the University of Illinois.

Tennessee University.—C. Elmer Wylie has been appointed assistant in dairying beginning June 15.

Utah College and Station.—The station office building has been thoroughly renovated and the station library rearranged to make its material more readily accessible. The mailing service for all publications of the institution, including those of the college, station, and extension division, has been reorganized to promote efficiency in sending out printed matter. A conference of the agronomy workers of the eleven Rocky Mountain and Pacific Slope States was held at the college July 18–20.

N. I. Butt, fellow in agronomy, has been appointed assistant agronomist and H. P. Anderson assistant chemist and bacteriologist. Other appointments in the station include Orson P. Madsen as assistant poultryman, vice A. D. Egbert, resigned; N. E. Edlefsen as assistant meteorologist; and W. J. Merrill as secretary to the director. George Stewart and H. R. Hagan, instructors in agronomy and entomology, respectively, have been granted leaves of absence for the ensuing year to pursue graduate work in Cornell and Harvard universities.

The dinterous family Scatopside. Melander	465
Notes on beet or mangold fly, Imms.	466
The dipterous family Scatopsidæ, Melander. Notes on beet or mangold fly, Imms. The yellow currant and gooseberry fruit fly (Epocha canadensis), Whitney	466
Life histories and methods of rearing Hessian fly parasites, Packard	466
The glossiness of tsetse flies, Hegh	466
A chemotropic response of the house fly (Musca domestica), Richardson	466
Flytraps and their operation, Bishopp. Phyllophaga Harris (Lachnosterna Hope): A revision of the synonymy, Glasgow.	466 467
On certain beetle larvæ found in sugar plantations, van der Goot	467
The cassava grubs, Leefmans	467
The Mexican cotton boll weevil	467
The turnip gall weevil.	467
The turnip gall weevil. The corn and cotton wireworm in relation to cereal and forage crops, Gibson	467
On the biology of the Gramang ant (Plagiolepis longipes), van der Goot	467
Transferring bees, Millen	467
Fourteenth report of Illinois State Beekeepers' Association, compiled by Stone	467
Bramble bees and others, Fabre, trans. by Teixeira de Mattos	468
The hunting wasps, Fabre, trans. by Teixeira de Mattos. A survey of the zoocecidia on species of Hicoria caused by parasites, Wells	468
A new out pest (Tarsonemus spirifex), the out mite, Schoevers	468
The red spider on cotton and how to control it, McGregor	468
FOODS—HUMAN NUTRITION.	
On the digestibility of bread.—I, Salivary digestion in vitro, Blake	468
34'11' 11 1' / 4 37 1-1	469
Nutrition investigations upon cottonseed meal, I, Richardson and Green	469
Commercial possibilities of the goosefish, Smith	469
Caviar: What it is and how to prepare it. Radcliffe	470
Fermented milk in infant feeding, Mucklow	470
Egg substitutes, Gerber. The use of wild plants as food by Indians, Wilson.	470
The use of wild plants as food by Indians, Wilson	470
Dandelions as food, Brewer and Canon. The use of horse-chestnuts in human nutrition, Serger	470 470
The culture, extractive content, and preservation of edible fungi, Falck	470
Utilization of honey and wax, Tinsley	470
[Food, drug, and dairy inspection]	470
[Food and drug inspection], Ladd and Johnson	470
Tenth biennial report of the dairy and food commissioner of Oregon, Mickle	470
Preliminary report of the dairy and food commissioner for 1915, Foust	470
Fifteenth annual report of the food and drug commissioner, Frary	471
Biennial report of the dairy and food commissioner of Wisconsin, Emery	471 471
The laws relating to the manufacture and sale of food products. Unique nonrefrigerative methods of food, Lodian.	471
What every housewife should know, Waldron.	471
Rise in British food prices, Washington.	471
Retail prices, house rent, and cost-of-living indexes, Knibbs	471
The dietary at the New York City Municipal Sanatorium, Wilson and Rathbun.	471
A week's menu for the average Filipino family, Herrera	471
The dietary of the field laborer in Spain. An experiment in the feeding of undernourished school children, Schmitt	471
The essential factors in a successful diet, McCollum	471 472
Vitamins and complementary food ingredients, Boruttau.	472
Vitamins and nutritional diseases.—A stable form of vitamin, Seidell	472
The growth of young chickens under laboratory conditions. Drummond	472
The growth of rats upon artificial diets containing lactose. Drummond	472
The action of Sardinian lactic acid on human metabolism. Fidanza	472
Relative toxicity of substances found in foods, Cook and Elliott.	473
Fate of inorganic nitrogen in metabolism of dog, Caldwell and Clotworthy Nitrogen metabolism during pregnancy, Wilson	473
Acidosis in diabetes, Woodyatt	473 473
Chemical means of protection against the cold, Montuori and Pollitzer	474
	11-1
ANIMAL PRODUCTION.	
Studies on the nutritive value of straw materials, von der Heide et al	474
Chemical determination of value of straw meal as feed material, Kerp et al	474
,,,,,	

The line and the life is a second of the life is a sec	Page.
Feeding experiments with disintegrated rye straw, Stutzer	474
On the digestibility of pine needles, Stutzer and Haupt.	474
Experiments with sphagnum turf as a feeding stuff, Stutzer	474
Experiments with sphagnum turf as a feeding stuff, Stutzer. Cattle feeding.—XI, Winter steer feeding, 1914-15, Skinner and King.	475
1/11a1 DITPOSE CALLIE. Mackenzie	476
Sheep feeding.—V, Fattening western lambs, 1914–15, Skinner and King	476
Wool studies: Washing before shearing; time of shearing. Hammond.	477
Alfalfa as a hog feed. Some pasture crops for hogs Peters and Goiken	478
Concentrates for growing chicks and for laying stock Juli	479
Skim milk for laying hens, Lewis. External characters as indications of egg production, Kent.	479
External characters as indications of egg production, Kent	480
Occurrence and significance of Bacterium pullorum in eggs, Rettger	481
DAIRY FARMING—DAIRYING.	
The mineral metabolism of the milch cow; first paper, Forbes, Beegle, et al	481
Silage made from oats and tares as a food for milking cows, Oldershaw	481
Influence of temperature on proteolytic activity of lactic ferments, Gorini	481
Experiments in Sweden on the prolonged pasteurization of milk, Barthel	482
Studies on Swedish Emmental and large grad change Downward, and Herland	482
Studies on Swedish Emmental and large-eyed cheese, Rosengren and Haglund.	483
Cheese making, Stahl	483
VETERINARY MEDICINE.	
Report of Bengal Veterinary College and Department, 1914-15, Smith and Kerr.	483
Annual report on the Punjah Veterinary College, 1914-15. Pease et al	483
Utilization of sucrose and inverting power of the blood serum, Kuriyama	483
Intravenous injection of magnesium sulphate for anesthesia, Auer and Meltzer.	484
Some fallacies regarding phenol, Wilbert	484
Immunity produced by instillation of horse serum into nose, Sewall and Powell.	485
Immunity conferred by the transfer of serums, Sewall et al.	485
Serum antitrypsin during inanition, Jobling and Petersen.	486
The coagulation reaction in anaphylactic shock, Hirschfeld and Klinger	486
Veccine treatment Halton	486
Vaccine treatment, Hektoen The etiology of rat-bite fever, Blake	
The etiology and treatment of rat-bite fever, Tileston	487
The enlowing and treatment of fat-bite lever, Theston	487
Chinese animal hides, skins, and bristles, Shand.	487
Resistance of Bacillus anthracis spores to high temperature, Malone and Shanly.	487
Experiments upon the transmission of rinderpest, Ward et al	487
The preparation and use of antirinderpest serum, Ward	487
The heat resistance of bacterial spores, Shanly	487
On the pathology of bovine actinomycosis, a preliminary report, Griffith	488
Bucillus enteritidis as cause of infectious diarrhea in calves, Meyer et al	488
Observations of keratitis infectiosa of the reindeer, Avid	488
Coccidiosis of Egyptian sheep and goats, Askar	488
Hog cholera: Its control and eradication, Strodtman and West	488
Production of clear and sterilized antihog-cholera serum, Dorset and Henley	488
Ascariasis in the horse and swine, Thum	489
A clinical study of equine strongylidosis, Leneveu	489
The poisonous effects of the rose chafer upon chickens, Lamson, Jr	489
RURAL ENGINEERING.	
Engineering geology, Ries and Watson	489
Engineering geology, Ries and Watson	489
Water resources of the State of Oregon, Lewis	489
Report of progress of stream measurements for 1914, Peters et al	490
Water samples, Heimburger	490
Status of activated-sludge sewage treatment, Hammond	490
Reclamation Board Act of the State of California, 1915.	490

EXPERIMENT STATION RECORD.

Vol. 35.

OCTOBER, 1916.

No. 5.

The seventh session of the Graduate School of Agriculture, under the auspices of the Association of American Agricultural Colleges and Experiment Stations, was held July 3-28 at the Massachusetts Agricultural College. This institution has a regular graduate school, whose director and faculty were especially active in assisting the dean in planning and conducting this summer graduate school. The attempt was made to develop a more systematically organized plan of work at this session than had hitherto been undertaken. This plan involved work in two main lines. One of these included progressive consideration of the fundamental factors involved in the growth of plants and animals. The other dealt with the economic and social factors which enter into the development of profitable systems of agriculture and well-organized rural communities. The fact that the Massachusetts College has been giving special attention to the problems of rural economics and sociology made it very appropriate that an effort should be made to summarize the present status of knowledge along these lines in their particular relations to American conditions.

The total enrollment of instructors and students was one hundred and ninety-eight, representing twenty-seven States, besides the District of Columbia, Porto Rico, England, Canada, and the Transvaal.

There were forty-five persons who gave instruction as lecturers or leaders of seminars, and about forty others who participated in the formal presentation of matter in the seminars and conferences. The faculty included representatives of the Universities of Illinois, Missouri, Chicago, Harvard, and Yale, the United States Department of Agriculture, the Missouri Botanical Garden, Amherst College, London Hospital Medical College, Massachusetts State Board of Education, Vermont Department of Agriculture, Kalamazoo Normal School, and the agricultural colleges and experiment stations in Indiana, Kansas, Massachusetts, New Hampshire, New York, Ontario, Oregon, Pennsylvania, Vermont, West Virginia, and Wisconsin. Dr. A. C. True of the States Relations Service again acted as dean, with Dr. C. E. Marshall, dean of the Graduate School of

401

the Massachusetts Agricultural College, as assistant dean and Mr. E. H. Forbush of the college as registrar.

At its public opening exercises the school was welcomed to the Massachusetts Agricultural College by President K. L. Butterfield, and the Granges of New England were represented by Rev. J. H. Hoyt. Director H. P. Armsby, of Pennsylvania, as chairman of the association's committee on graduate study, presided at this meeting and spoke on the development of graduate study in agriculture in the United States. He gave recently collected statistics showing that about one thousand graduate students preparing for work along agricultural lines were enrolled in the land-grant universities and colleges during the past academic year. Dean True, of the Graduate School, outlined briefly the objects for which the school was established, the reasons for the particular courses of instruction offered at the seventh session, and the intellectual and social advantages to be derived from the contact of instructors and students in such a school.

Dr. True pointed out that in our time "education and research more and more involve the harmonious working together of groups of individuals who are willing to put away selfish ends for the common good. In a vast country like our own with a population drawn from all quarters of the globe, and with an almost infinite variety of environmental conditions, associations of scholars and investigators from many different regions, whether their work deals with subjects remote from practical affairs, or as in the case of most of us with matters of vital concern to great industries, is of great importance as an aid to that mutual understanding on which the life of our nation and the perfecting of our civilization depend. For after all, as recent events in the world's history have shown, public opinion and governmental action depend, more largely than is generally recognized, on the modes of thought which are developed in the institutions of higher learning.

"Such an organization as this Graduate School, having behind it the associated universities and colleges represented in the Association of American Agricultural Colleges and Experiment Stations, may also be influential in shaping the ideals and standards of agricultural scholarship and research. If through our discussions here we are able to carry back to our respective institutions suggestions for the improvement of courses of instruction and methods of research and to stimulate faculties and students to more thorough work, we shall have made a valuable contribution to those influences which are to determine the success of the great movement to raise American agriculture and country life to the highest possible level.

"Since the last session of our school this movement has made unusually rapid progress. The permanent national system of agricultural extension education, provided for in the Smith-Lever Act of 1914, has already become well organized and attained great dimensions. In over one thousand two hundred counties, spread over the entire country, extension agents are regularly working. Supporting these local forces are about one thousand five hundred extension specialists and administrative officers maintained by the state colleges and the Department of Agriculture. At least one thousand teachers are giving instruction in agricultural subjects in our colleges, and the numbr of students in four-year courses of agriculture has risen from 14,000 in 1913, to 19,500 in 1915. The past year 4,900 secondary schools gave agricultural courses attended by 95,000 students, as compared with 1,400 schools and 30,000 students two years before. force employed in our agricultural experiment stations has risen to 1,860 and the income of the stations in 1915 was \$5,286,000. force employed in the Department of Agriculture is over 16,000 and its income about \$25,000,000.

"The demand for thoroughly trained and efficient workers in agricultural lines, whether in research, education or farm practice, has never before run so far beyond the supply. The rsponsibilities of the leaders in the agricultural movement have never been so heavy. Their encouragements have never been so great. This body of young men, who have already been trained in our higher institutions of learning and many of whom are already engaged in teaching or research, have before them exceptional opportunities for leadership and high success. The incentives to thorough preparation and the most strenuous endeavor are of the highest and broadest character. nature's secrets and thereby advance science and human welfare, to inspire and instruct a vast multitude of men, women, and children in colleges, schools, and millions of homes, to lay a firm and safe foundation for the permanent existence and prosperity of the United States and in large measure of all the world—these are the appropriate tasks of agricultural scholars and scientists."

The course on growth consisted of twenty lectures and nineteen seminars, covering the four weeks of the session and including the general subjects of the dynamics and elemental chemical synthesis of growth, cell entity or growth organization, and growth relations. In the first week Prof. C. M. Child, of the University of Chicago, gave five lectures on the general dynamics of protoplasm, the organic individual, unity and order in growth, development and evolution, and reproduction. He paid special attention to an analysis of his own experimental studies on the dynamics of form production, as shown by some of the lower animals. The presence of a chief axis

of growth and of minor axes was recognized, and the results of studies on planarian worms and on hybrids were held to demonstrate the existence of metabolic gradients along these axes. The behavior of an excised piece of the body of one of these animals was shown to have a definite relation to the region of the body from which it was taken, and the reconstitution of parts was shown to proceed at a rate and in a way that were in definite relation to the metabolic gradient involved.

The dedifferentiation of the cells of the bodies of these sample animals was affirmed. The importance of dedifferentiation in producing the embryonic condition in somatic cells was emphasized in its relation to rejuvenescence and reproduction. The theory of a germ plasm, universal in the Metazoa, contained in cells separate from the soma was held to be compromised, if not invalidated, by the fact that differentiated somatic cells in these simple organisms can be brought into the embryonic condition and made to function in the reconstitution of the organism. Reproduction becomes a phase of general growth dynamics and related to metabolic factors.

Dr. V. E. Shelford, of the University of Illinois, as leader of the seminars, supplemented Professor Child's discussion by accounts of the studies by himself and others regarding the intimate influence of environmental factors on metabolic processes, interpreting life

cycles, and even morphogenesis, in these terms.

In the second week Dr. Benjamin Moore, formerly of the University of Liverpool and now connected with the London Hospital Medical College, presented the elemental chemical synthesis of growth. He discussed, among other things, the energy transformations in metastable inorganic colloidal systems and the morphological changes accompanying them, and showed how certain products of the inorganic systems closely simulate living structures. It thus appears altogether probable that in the process of evolution inorganic matter passes into organic through a synthesis involving an uptake in energy and an increase in molecular complexity. The cell as an energy transformer was considered, and the relation of the action of light on formaldehyde in high concentrations and upon organic products formed in life processes was demonstrated. Some attention was also given to other photosynthetic actions and the theories of photosynthesis, as well as to the relationships of a physico-chemical basis for the origin of life to Pasteurism, evolution, and heredity.

Dr. E. V. McCollum, of the University of Wisconsin, as leader of the seminars that week, discussed the fundamental food requirements of animals in the light of recent investigations on the kinds and combinations of food nutrients and feeding stuffs necessary for normal growth in small and large animals—rats, swine, and cattle. He emphasized especially the importance of exact knowledge as to the source, chemical composition, and relative proportions of the nutrients used, and the essential need of the presence of food, though in very small amounts, of at least two unknown substances.

In the third week, Dr. B. M. Duggar, of the Missouri Botanical Garden, gave five lectures on cellular entity. In these the present-day knowledge and theories were clearly and impartially summarized, including the morphology, structure, and chemical composition of the individual cell, semipermeable membranes and related phenomena, cell correlation in relation to growth, cell organization in respect to reproduction, and the activities of the cell in regeneration. At the seminars Dr. L. J. Henderson, of Harvard University, took up the subject in its purely physico-chemical aspects and dwelt particularly on the laws and hypotheses fundamental to our knowledge of the cell, together with some of the more philosophical considerations of the subject.

Growth relations was the general topic of the lectures of Dr. H. C. Cowles, of the University of Chicago, during the last week of the course. Among the subjects treated were germination and growth, vegetation activity in relation to light, water, etc., and reproductive behavior as influenced by external factors. Plant interrelations were also considered, such as antagonisms, illustrated by parasites and epiphytes, the struggle for existence, including the ecology of weeds; beneficial relations, as illustrated by soil bacteria and fungi, and reciprocal relations, as exhibited by legumes with bacteria, trees with root fungi, etc. In connection with mass relations, soils and climates as factors in associational development and change in composition in relation to change in environment were discussed, and finally the application of ecological factors to problems of crop production was instructively presented. At the seminars Dr. Henderson discussed the physico-chemical properties of environmental factors, with special reference to hydrogen, oxygen, and carbon, in their more important combinations, and closed with some of the philosophical aspects of environment.

Parallel with the general course on growth an adjunct course which embraced a systematic review of physico-chemical elements involved in growth and their relation to biological processes was given by Messrs. Anderson, Itano, Robbins, Chapman, and Clark of the Massachusetts College faculty.

A week was devoted to discussions of the problems of education with special reference to the training of students along agricultural lines. Dr. W. C. Bagley, director of the school of education of the University of Illinois, gave five lectures on the foundations of peda-

gogy. He argued that not only knowledge but "skill" is a legitimate and important end of education, whether the subject taught is what is ordinarily called cultural, such as language and mathematics, or technical, as engineering and agriculture. The interrelations of technical and cultural aims in education were also dwelt upon. A clear and impartial résumé of the experimental researches on the disciplinary value of various studies was given, with the conclusion that the evidence thus far accumulated indicates that there is a certain disciplinary result which may be transferred from one study to another but that this is not so large as has been commonly held by the friends of the old classical education.

Dean W. W. Charters of the School of Education of the University of Missouri presented some of the principles on which methods of teaching should rest. He laid special stress on the principle that the normal mental process in learning is to work from problems toward their solution. A problem arising in the experience of the student or being presented to him by his teacher, the learner may become in large degree his own instructor, especially if the solution is of vital interest to him. The application of this principle would in many subjects result in economy of mental effort, increase of interest, and more permanent results. Good method should always culminate in elaborated and well-organized knowledge.

At the seminars the practices of teaching various agricultural subjects were presented by Dean R. L. Watts of Pennsylvania State College on vegetable gardening, Prof. C. G. Woodbury of Purdue University on pomology, Prof. C. A. Zavitz of Ontario Agricultural College on agronomy, and Prof. J. E. Rice of Cornell University on poultry husbandry, as well as by members of the Massachusetts College faculty and others. On Saturday a conference on the training of men for agricultural service was led by President H. J. Waters, of the Kansas Agricultural College, who dwelt on the nature and function of the college course in its adaptation to this end, and by Prof. G. A. Works of Cornell University who discussed the relation of the agricultural college to the preparation of teachers of agriculture in secondary schools.

The conference was followed by a round-table discussion by teachers of secondary agriculture on the value of the college courses in agricultural education as a means of preparation for teaching agriculture, this meeting being one of the series of conferences held during the past year through the coöperation of the United States Bureau of Education and the States Relations Service. During this educational week emphasis was often laid on the importance of training in the principles and methods of education for students intending to become teachers of agricultural subjects in colleges or schools.

The economic factors connected with agricultural production were discussed during the second week of the school. Mr. E. H. Thomson, of the Office of Farm Management, with the aid of lantern slides showed the geographical range of different staple crops and the results of surveys by that office to determine the various natural and economic factors which underlie the successful production of crops. Prof. J. A. Bexell, of the Oregon Agricultural College, gave five lectures on agricultural accounting and business methods, in which he illustrated and emphasized the importance to the farmer of definite knowledge regarding the actual income and outgo connected with his farming operations.

At the seminars of this week the different factors of production and their correlation were presented by Prof. M. B. Cummings of the University of Vermont for pomology, Prof. L. C. Corbett of the Bureau of Plant Industry for market gardening, Prof. E. A. White of Cornell University for floriculture, Prof. E. Rasmussen of the New Hampshire College for dairy husbandry, and Prof. J. E. Rice for poultry husbandry, and these subjects were further discussed by members of the Massachusetts College faculty representing the respective industries. During this week also the Scientific Basis of Agriculture formed the subject of two evening conferences, led by Director W. H. Jordan, of the New York Experiment Station, who emphasized the importance of strictly scientific investigations as a basis for the improvement of agricultural practice, and the necessity of employing thoroughly trained experts to give their time fully to such work.

Distribution and marketing of farm products were the economic subjects discussed during the third week. Dr. L. D. H. Weld, professor of business administration of the Sheffield Scientific School of Yale University, defined marketing in its relations to the general subject of economics, described and discussed the functions of middlemen, the factors involved in the cost of distribution of agricultural products, the weaknesses of present methods of marketing and their remedies, and the methods which should be used in investigating marketing problems. He compared the methods of marketing agricultural and manufactured products, and illustrated his subject with numerous references to his own studies in both fields.

Mr. C. J. Brand, Chief of the Office of Markets and Rural Organization, described the federal and state organizations for improving market conditions, and discussed uniform standards of market grades and packages, methods of sale of agricultural products, cooperative marketing in the United States, and the cotton marketing system in this country.

At the seminars many phases of the marketing problems as related to various agricultural industries were presented and discussed.

Mr. H. C. Thompson, of the Bureau of Plant Industry, spoke on vegetables, Professor White on flowers, Professor Rasmussen on dairy products, and Dr. E. W. Benjamin, of Cornell University, on poultry products. Mr. V. K. McElheny, of New York City, president of the American Fruit and Produce Auction Association, presented the function of the auction as a marketing agency; Mr. C. R. White, of Ionia, N. Y., considered the place of the cooperative exchange; Mr. W. J. Thurston, of the Cooperative Flower Exchange of Boston, dealt with the practical problems connected with the sale of flowers; Mr. E. S. Brigham, commissioner of agriculture of Vermont, treated of the sale of dairy products; and Mr. F. G. Urner, of New York City, and Mr. H. J. Bird, of the produce department of Swift & Co., dealt with the sale of poultry products. A number of members of the Massachusetts Agricultural College faculty supplemented these discussions with matters connected with marketing as related to their specialties.

At the evening conference, Dean J. L. Coulter, of the College of Agriculture of the University of West Virginia, led the discussion on farm finance and explained the principles and operations of the Federal Farm Loan Act. At the Saturday conference on the topic, Making the Farm Pay, Prof. G. F. Warren, of Cornell University, discussed the factors of profit in farming in the light of certain farm management investigations in New York.

The work of this week showed how great has been the advance in recent years in the collection and consideration of definite data on marketing and other economic problems in agriculture in the United States, as well as the rapid progress in the establishment of state and federal agencies for the study of these problems and the giving of assistance in their practical solution.

In the fourth week, Prof. H. C. Taylor, of the University of Wisconsin, under the head of Land Problems, discussed the social and economic factors determining the types of farming and the proper degree of intensity of culture in agricultural production, the helps and hindrances to land ownership, the forms of land tenure, land values, capitalization, and amortization.

President Butterfield summarized in three lectures important results of his studies on organization as a condition of rural social growth. He defined rural organization as the systematic and progressive assembling of all those forces and agencies which make for the sound development of the business and life of rural people and for the adjustment of their highest welfare to the common good. Great stress was laid on the proper organization of the local rural community as a basis for organization in the broad units. In this connection he said:

"The local community becomes both the beginning and the end of social effort; the beginning because it is the most efficient method of correlation; the end because if you have a true rural democracy in a multitude of these small neighborhood units—that is, a multitude of groups of farmers, each group of which is reasonably prosperous, fairly free, and socially alive, then you have a national rural democracy, and you can not get it in any other way, because there is no such thing as a democracy made up of isolated individuals. The very essence of democracy is cooperation. But this cooperation is practicable only in small groups, not in the mass. In developing this community we shall need to define the community, to make a community study, to have a community plan, to have a community council or committee, to establish a community conference, and to have a physical community center.

"In the same fashion the State should be organized on behalf of rural improvement and adjustment. Without going into detail, this may be illustrated by two things that have been done in Massachusetts. The first was the organization of the Massachusetts agricultural development committee, which for a year has been working on the following task, not yet completed: (1) Outlining methods and plans for a study and mapping of the agricultural resources of the State; (2) outlining a plan for the development of agriculture and country life of the commonwealth; and (3) recommending the form of organization and work for different agencies interested in rural life and the best way of correlating their activities. Massachusetts has also a State federation for rural progress which attempts to serve as a sort of clearinghouse for all the different institutions of the State. Obviously these two agencies need correlation.

"In a broad sense (1) the goal of rural endeavor is to build an adequate rural civilization based on the interests both of the farming class (and the individuals who compose it) and of society as a whole; (2) the condition which most completely governs the rural social growth implied in achieving this sort of rural civilization is contained in the idea of organization, or the correlation of those forces and agencies on which we must mainly rely for improvement and adjustment; and (3) the practice of rural organization involves the utmost efficiency in each rural agency, the carrying out of definite plans or projects of improvement looking toward definite industrial and social ends, and the unifying of rural forces and agencies within certain geographical areas, notably in the local community and in each State as a whole."

Dr. Ernest Burnham, of the Normal School of Kalamazoo, Michigan, considered in two lectures the creative relation of leadership to rural organization. He defined the object of leadership to be the begetting, or discovery, of a dynamic sense of progress in individuals and institutions and the constant revivification of this sense in action.

At the seminars, Mr. C. W. Thompson, of the Office of Markets and Rural Organization, introduced the discussion of the community survey and the community club. Prof. John Phelan, of the Massachusetts College, spoke on the human element in rural improvement, and Dr. L. H. Bailey gave addresses on the characteristics and functions of the editor and the coming range in the work of the agricultural college. Dr. Bailev laid great emphasis on the need of thoroughly trained, competent, and academically free teachers and investigators, and deprecated what he considers the present tendency to impose too formal and binding requirements on college and station officers as exemplified in certain forms of so-called "projects." Several members of the Massachusetts College also took part in the seminars of this week. At the closing evening conference, Prof. E. L. Morgan spoke on a Massachusetts achievement in rural improvement, summing up what has been done in that State in a practical way in effecting local, county, and State organization for the advancement of agriculture and country life.

The Graduate School thus presented a well-rounded course, starting with the question of the origin of living from nonliving matter and dealing in order with the chemistry, physics, and biology of the soil; the growth relations of plants and animals; the economic factors of production, distribution, and marketing of farm products; and finally, with the potentialities and possibilities of life in the open country. The course recognized and emphasized the importance and significance of thinking out rural life problems "from the soil to the soul." The fundamental principles of common interest to all students of scientific agriculture were emphasized rather than economic applications in specialized lines of industry, no attempt being made to deal with any special line in a complete way. The course was especially suggestive to investigators and should have been helpful to those entering upon the work of investigation. Emphasis was constantly placed, directly or by inference, upon the importance of dealing with agricultural problems at first hand and of having accurate, live, firsthand information for this purpose. This was most strikingly illustrated in the case of the discussion of questions of rural economics and sociology.

As regards the amount and high character of the work done, this session of the Graduate School was fully as important and successful as any which have preceded it. The local arrangements for the school were very good, and the courses of instruction were loyally supported and largely attended by the relatively large force now employed by the Massachusetts College. The attendance from outside, however, while representing all sections of the United States, was disappointingly small in the aggregate.

It is evident that the causes which have operated to keep down the attendance at other recent sessions have increased in influence and were not overcome by unusually active measures to advertise the school this year. Among these hindrances, the most potent seem to be the great increase of summer work and other burdens on members of the college faculties, the opening up of greater opportunities for regular graduate work in agriculture at numerous institutions, and the inability of the Association's Graduate School, under present conditions, to give credit for the work done there which might be used elsewhere as part of the requirements for advanaced degrees.

The future status of this Graduate School, therefore, needs very careful consideration by the association and its constituent institutions when the question of the next session is taken up.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Biochemical changes in cotton seed in storage, J. B. RATHER (*Arkansas Sta. Bul. 125* (1916), pp. 3-18).—Studies are reported of the changes in stored cotton seed with reference to the loss of vitality and the availability from the standpoint of the cotton-seed-oil mill and the live-stock feeder.

The fat in ground cotton-seed was found to hydrolyze rapidly into fatty acids. This hydrolysis may amount to 85 per cent of the fat in three weeks.

In cotton-seed from seed cotton gathered dry and stored for three weeks in a common farm cotton house and in a cotton-oil mill seed house in lots of 4,500 and 7,500 lbs., respectively, no appreciable changes except a reduction in the moisture content occurred. Dry cotton seed stored in a common farmhouse in a 3,000-lb. lot in a pile 12 by 12 by 4 ft. did not deteriorate during the period of oil-mill operation. A slight loss of moisture in the samples caused correspondingly small increases in the percentage of protein and fat. The free fatty acids in the fat and the total acidity of this seed did not increase to any significant extent. Cotton seed stored in an oil-mill seed house in a 5,000-lb. lot in a pile 12 by 12 by 6 ft., dried out in storage and then heated. During heating the free fatty acids in the fat increased from 2.26 to 11.89 per cent, and the total acidity from 28 cc. of normal alkali per kilogram of seed to 91 cc. A slight protein hydrolysis was observed.

The free fatty acids in the fat of samples of fresh cotton seed at the time of picking was less than 2 per cent of the fat, and the total acidity of the seed was about 26 cc. of normal alkali per kilogram of seed. It is deemed probable that the increase in the free fatty acids and in acidity is due to heating and not to aging of the seed. Cotton seed stored in lots of 1,000 lbs. did not deteriorate in storage.

It is indicated that in extreme cases of heating the carbohydrates, fats, and proteins of the stored seed are attacked, and analytical data submitted show that the hydrolysis of the fat may reach 70 per cent and that of the protein 35 per cent. When cotton seed heats the fats decompose the most readily, and it was observed that this may take place to a considerable extent before the other constituents begin to undergo change. The acidity of fresh cotton seed is regarded as due only partially to fatty acids from the fat, but it is pointed out that in heated seed the content of free fatty acids is as great as, or greater than, is necessary to account for the total acidity. It is concluded that unless cotton seed heats badly the meal made from it will be as valuable for feeding as meal made from unheated seed, but that the oil from even slightly heated cotton seed is worth considerably less than oil from fresh seed.

Note on American charlock oil, H. S. Bailey and L. B. Burnett (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, p. 429).—The authors report the physical and chemical constants of the expressed oil, the ether extract, and the petroleum ether extract obtained from pure charlock (Brassica arrensis) seed. It is indicated that the oil can be used in soap making and possibly in cheap paints. Its value for food purposes has not been investigated.

Ceanothus velutinus (snow brush) as a source of wax and tannin, C. C. Scalione and H. S. Blakemore (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 411-413, figs. 2).—C. velutinus was found to contain 7.3 per cent wax and 17.3 per cent of tannins. The wax was largely composed of free hydrocarbons and free cerotic acid, together with palmitic and stearic acids in combination with ceryl and myricyl alcohols. A trace of glycerids was also indicated. The tannin was of the catecholic variety. Tanning tests have indicated that a suitable extract can be prepared from the leaves.

Cyanogenesis in plants. Studies on Tridens flavus (tall red top), A. Viehoever, C. O. Johns, and C. L. Alsberg (Jour. Biol. Chem., 25 (1916), No. 1, pp. 141-150).—The presence of hydrocyanic acid in the common grass T. flavus, has been confirmed. Considerable quantities were present in the plants collected in August, while only a trace was found in the plants collected in September and none in the October plants. The maximum amount of acid was found in the inflorescence tops, with only a trace in the roots and none in the seeds.

No free hydrocyanic acid was obtained by direct distillation with steam. Previous maceration with water resulted in a loss of acid. When tartaric acid was present during the maceration of the plant all of the cyanid was recovered. In the presence of sodium hydroxid the loss of added cyanid was complete. This loss during maceration is deemed to be probably due to a chemical reaction.

The presence of an amygdalin-hydrolyzing enzym in T. flavus was also established.

The separation of autogenous and added hydrocyanic acid from certain plant tissues and its disappearance during maceration, C. L. ALSBERG and O. F. BLACK (Jour. Biol. Chem., 25 (1916), No. 1, pp. 133-140).—It has been shown that "the leaves of Prunus virginiana must be distilled with acid four hours before all of the hydrocyanic gas is liberated, whereas in Andropogon and Panicularia less than one hour is sufficient to liberate all hydrocyanic acid present."

When plant tissues which contain hydrocyanic acid, or to which cyanid has been added, are macerated a certain portion of the hydrocyanic acid is converted into such form as not to be recoverable by distillation with sulphuric acid. This is not due to the action of enzyms or to the presence of glucose. It is indicated that in determining the hydrocyanic acid in plants several methods in corroboration of one another should be used.

The distribution of maltase in plants.—I, The function of maltase in starch degradation and its influence on the amyloclastic activity of plant materials, W. A. Davis (Biochem. Jour., 10 (1916), No. 1, pp. 31-48, figs. 2).—It is indicated that maltase is probably present in all plants in which starch degradation occurs. The facts that the enzym is endocellular and therefore not easily extracted and is also unstable account for the failure of earlier workers to detect the presence of the enzym generally. The action of the enzym is greatly inhibited or even destroyed at temperatures above 50° C. and is destroyed by ordinary alcohol or chloroform.

Maltase occurs in considerable quantities in germinated and ungerminated cereals, and is probably localized mainly in the aleurone layer of the endosperm. If the kilning has been at a temperature sufficiently low not to destroy the enzym it may be present in malt. Its presence in malt or malt diastases would explain the formation of glucose from starch, which has previously been attributed to other causes. Maltase of plants does not act directly on starch or dextrins, but only on maltose which has been formed by diastatic enzyms.

A direct cleavage of glucose from starch never occurs. The action of the enzyms of germinated barley on starch is very similar to that of taka-diatase, the latter, however, being richer than the barley in maltose-forming enzyms, so that the dextrin stage is passed through more rapidly. In either case the glucose is formed by the action of maltase on maltose. In determining the diastatic activity of plant material in preparations such as taka-diatase and pancreatins the presence of maltase should be taken into account.

The distribution of maltase in plants.—II, The presence of maltase in foliage leaves, A. J. Daish (*Biochem. Jour.*, 10 (1916). No. 1, pp. 49-55).—The presence of maltase in the leaves of Tropæolum, potato, dahlia, turnip, sunflower, and mangold, whether picked at night or in the daytime, has been demonstrated by the production of reducing sugars through the action of macerated leaves on soluble or gelatinized starch. In the presence of an excess of starch the conversion is generally incomplete. Under these conditions the action of the endocellular maltase is limited because of its low solubility and power of diffusion. On this account maltose is nearly always found among the products.

The distribution of maltase in plants.—III, The presence of maltase in germinated barley, A. J. Daish (Biochem. Jour., 10 (1916), No. 1, pp. 56-76, fig. 1).—The presence of maltase which hydrolyzed maltose to glucose in airdried germinated barley was demonstrated by allowing the finely powdered grains to act on starch or maltose at 38° C. The action on starch is very similar to that of taka-diastase, which contains maltase in addition to the ordinary diastatic enzyms.

The action on germinated barley probably takes place in the following series of stages: Starch—soluble starch—dextrins—maltose—glucose.

The self-digestion of the barley starch is largely inhibited during the process of digestion of added starch until the greater part of the latter is converted into glucose. A correction for the enzymic material used, therefore, can not be applied by carrying out a control in the presence of water alone.

In the digestion of gelatinized starch by germinated barley dextrin, maltose, and glucose are found even after prolonged periods. The glucose steadily increases, however, in amount during the whole period of digestion, with a consequent decrease of the other saccharids.

Observations on beet and potato tyrosinase, M. Gonnermann (Chem. Ztg., 40 (1916), No. 16-17, pp. 127, 128).—The author has demonstrated that the tyrosinase prepared from the potato possesses agglutinating properties which are specific for sheep corpuscles. The tyrosinase from beet juice possessed no agglutinating property but was hemolytic. This latter property is attributed to the presence of saponins which are so combined with the enzym as to make their complete separation impossible. The presence of the saponin was established by confirmatory tests. The potato tyrosinase used was a glycerin extract 14 years old but as active as a fresh preparation.

The enzyms of cacao, H. C. Brill (Philippine Jour. Sci., Sect. A, 10 (1915), No. 2, pp. 123-133).—"The pulp surrounding the cacao bean contains a greater number of enzyms than the fresh bean itself. The pulp shows activity for the enzyms casease, protease, oxidase, raffinase, and invertase. The fresh bean gave reactions for casease and raffinase, and very strong reactions for oxidase. The fermented bean reacted for casease, protease, oxidase, diastase, raffinase, and invertase."

Protease and invertase were present in the fermented bean as well as in the pulp, but were absent in the fresh bean. It is indicated that these enzyms must have penetrated the membrane surrounding the bean during fermentation. Diastase was also present in the fermenting bean, which was probably devel-

oped in the bean during the process of fermentation. It is concluded that "the presence of these enzyms undoubtedly influences the character of the fermentation and that temperature control during fermentation is necessary in order that they may not be destroyed."

Standard methods of sampling and analysis and standard samples, W. F. HILLEBRAND (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 466-469).— This aricle reviews the subject in brief and gives the standard methods recognized by courts of law in the United States, the methods not having legal recognition but approved by scientific or technical organizations, and the methods in use in laboratories of certain industrial establishments.

A diagram for the calibration of volumetric apparatus and the reduction of the volumes of liquids to a standard temperature of 20° C., H. C. Deming (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 451-453, figs. 3).—This article describes in detail the construction and use of the diagram which the author has devised for the rapid calibration of volumetric apparatus and the reduction of volumes of liquids to standard temperatures.

The admissibility of ammonium-magnesium phosphate as a form in which to weigh phosphoric acid, W. Jones (Jour. Biol. Chem., 25 (1916), No. 1, pp. 87-91).—Analytical data submitted indicate that in the quantitative determination of phosphoric acid the conversion of ammonium-magnesium phosphate into magnesium pyrophosphate is superfluous, since accurate and concordant results can be obtained by direct weighing of the crystalline precipitate. When dry the ammonium-magnesium phosphate can be easily and completely removed from the filter paper.

Estimation of carbon dioxid as barium carbonate applied to the Marr method for determination of carbonates in soil, C. J. Schollenberger (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 427, 428).—Experimental data obtained at the Ohio Experiment Station from a series of six soils by boiling with 1:10 hydrochloric acid at atmospheric pressure and by several modifications of the Marr method (E. S. R., 22, p. 511) are submitted.

A comparison of the permanganate methods for the determination of required oxygen, J. H. Sachs (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 404-406).—Analytical data obtained from a study of the various modifications for the determination of required oxygen in water are submitted. The method described by Thresh (E. S. R., 29, p. 506) of titrating in an acid medium after incubating at 37° C. is considered to be the best.

The analysis of proteins.—I, The estimation of arginin by decomposition with alkali, R. H. A. Plimmer (Biochem. Jour., 10 (1916), No. 1, pp. 115–119).—Experimental data indicate that arginin can be accurately estimated by boiling with 20 per cent sodium hydroxid instead of 50 per cent, as originally recommended by Van Slyke (E. S. R., 26, p. 22). The loss of determinations through the action of the alkali on the glass is thus avoided. Copper flasks were not found satisfactory, especially in the presence of histidin, as under these conditions the histidin undergoes considerable decomposition. Boiling in a glass flask causes a slight decomposition of histidin, but the error is practically negligible. It has been found to be more convenient to add an equal volume of 40 per cent NaOH than to weigh the correct amount of solid reagent. By using a solution of alkali a larger volume of liquid is contained in the flask, which obviates the subsequent distillation after the reaction is complete, as is necessary in the original procedure.

For the determination of the total nitrogen of the bases it is recommended to use a fresh portion of the solution of the bases rather than the residue from the arginin estimation, on account of the unavoidable bumping and consequent loss of nitrogen.

The recovery of copper sulphate from the filtrates in sugar determinations by using Fehling's solution, KRUMHAAR (Chem. Ztg., 40 (1916), No. 24, p. 174).—The following procedure is recommended:

The clear filtrate is sufficiently heated on the water bath and enough sugar solution added to reduce the copper. The precipitated cuprous oxid is washed several times by decantation, filtered on a porcelain filter, and washed free from alkali. It is then treated in a beaker with 200 cc. of concentrated hydrochloric acid, heated on the water bath, and the copper oxidized by the repeated additions of small amounts of hydrogen peroxid. The cupric chlorid solution thus formed is evaporated nearly to dryness, an excess of dilute sulphuric acid added, and the hydrochloric acid expelled by repeated evaporations to dryness and re-solution in water. Finally, the concentrated solution of copper sulphate is filtered and poured into about three volumes of 96 per cent alcohol. A pure, fine crystalline salt is obtained which is filtered on a Buchner funnel and washed with alcohol.

The estimation of reducing sugars by Kendall's solution and the construction of a table indicating the reducing power of levulose, EDITH G. WILSON and W. R. G. ATKINS (Biochem. Jour., 10 (1916), No. 1, pp. 137-141).— The authors have found Kendall's procedure, previously noted (E. S. R., 28, p. 111), for the determination of reducing sugars to be very satisfactory. The copper oxid is not, however, determined by the iodimetric method, as originally recommended, but by conversion of the cuprous into cupric oxid. The presence of citric acid interferes seriously with the accuracy of the method.

A table for converting milligrams of cupric oxid to milligrams of levulose is included.

The analysis of maple products.—VIII. The application of the conductivity and volumetric lead subacetate tests to maple sugar, J. F. SNELL and G. J. VAN ZOEREN (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 421, 422).—It has been demonstrated that "pure maple sugars converted into sirups give conductivity values and volumetric lead numbers within the limits found in genuine maple sirups."

See also a previous note (E. S. R., 35, p. 206).

Solubility data for various salts of lauric, myristic, palmitic, and stearic acids, C. A. Jacobson and A. Holmes (Jour. Biol. Chem., 25 (1916), No. 1, pp. 29-53).—Tabular data as to the solubility of the lithium, magnesium, beryllium, barium, lead, and silver salts of lauric, myristic, palmitic, and stearic acids are submitted in detail. The data include solubility figures in two or more of the following solvents: Water, ethyl and methyl alcohol, ethyl ether, benzene, ethyl acetate, methyl acetate, amyl alcohol, amyl acetate, chloroform, and acetone, at room temperature, 25, 35, and 50° C. wherever the boiling point of the solvent permitted. The preparation of the salts, together with the methods used for determining the solubility, is also described.

The data indicate that the solubility of all the salts of the four fatty acids in the various solvents tried is very slight. Considerable differences are found, however, not only among the several salts in the same solvent but also for the same salt in the different solvents. Methyl alcohol was found to be the best general solvent for these salts.

These data were obtained in connection with work on the constituents of alfalfa-seed oil, previously noted (E. S. R., 34, p. 710).

The separation of lauric and myristic acids from each other and from mixtures of other fatty acids, C. A. Jacobson and A. Holmes (Jour. Biol. Chem., 25 (1916), No. 1, pp. 55-61).—The authors describe a method for the separation of lauric acid when present in a mixture of myristic, palmitic, and stearic acids, and also a method for the separation of myristic acid from a

mixture of lauric, palmitic, and stearic acids. The methods are based on the differences of solubility of the lithium and magnesium salts of the acids in water and 50 per cent alcohol.

Determination of tartaric acid, B. G. HARTMANN, J. R. EOFF, and M. J. INGLE (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 422-425).—After preliminary experiments on the earlier methods for the determination of tartaric acid, the authors have modified the method of Halenke and Möslinger and describe their procedure as follows:

For wines 100 cc. of the sample is neutralized with sodium hydroxid, and to the neutralized wine is added a molecular equivalent in grams of powdered tartaric acid corresponding to the amount of alkali required for neutralization. After complete solution of the tartaric acid 2 cc. of glacial acetic acid and 15 gm. potassium chlorid, together with 15 cc. of 95 per cent alcohol, are added. The mixture is well stirred until precipitation has started and allowed to stand overnight at a temperature not above 15° C. The solution is then filtered through either a Gooch crucible prepared with filter paper pulp or a Buchner funnel fitted with hardened filter paper, using gentle suction. The precipitate is washed with three portions of 7 cc. each of a solution composed of 100 cc. of water, 15 gm. of potassium chlorid, and 20 cc. of 95 per cent alcohol. The precipitate and paper are transferred to the original beaker with 50 cc. of hot water. brought to the boiling point, and immediately titrated with tenthnormal sodium hydroxid, using phenolphthalein as indicator. A correction of 1.5 cc. added to the burette reading is necessary for solubility. This corrected reading, multiplied by 0.015 and subtracting the amount of tartaric acid added, is the total tartaric acid in the wine in terms of grams per 100 cc. Rochelle salts may be used in place of tartaric acid.

In artificial products containing free phosphoric acid and alcohol satisfactory results with the method could not be obtained. The results were consistently low, due to the formation of ester in the presence of the mineral acid. The amount of ester was found to increase with the age of the sample. To obviate this source of error 5 cc. of normal sodium hydroxid in excess of that required for neutralization was added to 50 cc. of the solution under examination, heated to boiling, and allowed to stand overnight. The determination was then carried out in the usual manner.

The analysis of nonalcoholic lemon and orange extracts, E. L. Redfer (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, p. 421).—After some preliminary experiments the method described by Howard (E. S. R., 20, p. 113) was found to be satisfactory and to yield concordant results.

Some qualitative tests for gum arabic and its quantitative determination, C. E. Waters and J. B. Tuttle (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 413-416).—The qualitative tests commonly recommended for gum arabic are briefly reviewed. The most characteristic test was found to be the precipitate with basic lead acetate. Mixtures of copper sulphate and sodium hydroxid and of neutral ferric chlorid and alcohol were also found to be valuable as confirmatory tests.

After considerable preliminary experimentation a quantitative procedure was devised and is described in detail.

On the drying of sugar beets and other agricultural products and by-products, A. Gröger (Arch. Chem. u. Mikros., 9 (1916), No. 1-2, pp. 1-47).—This article discusses the subject in some detail and indicates the economic importance of the drying of agricultural products. Some experimental and statistical data are included.

^e Ztschr. Analyt. Chem., 34 (1895), No. 3, pp. 263-293.

Evaporation of apples, J. S. Caldwell (Washington Sta. Bul. 131 (1916), pp. 7-110, figs. 24).—The author believes that under Washington conditions low-grade apples may be most easily and profitably utilized by the construction of evaporators.

The operation of small evaporating plants is not deemed profitable and is not recommended. An evaporator of a capacity of not less than 400 bu. of apples per day should be used to insure a safe margin of profit.

The kiln or hop drier, the tunnel evaporator, and what is termed the Carson-Snyder or all-purpose evaporator are recommended as adapted for use under Washington conditions. The kiln drier is considered slightly the cheapest, both in construction and operation, and gives excellent results with apples, but is not well adapted to the drying of peaches, berries, or prunes.

The construction, equipment, and operation of the three types of evaporators recommended is described in detail. Estimates on the construction and operation of the plants are also submitted. It is indicated that "1 bu. of C grade or of good cull apples will yield 6.75 to 7.5 lbs. of fruit having 25 per cent moisture content, the exact yield varying with variety as well as with size and quality of fruit."

The total cost of evaporation will also vary for the different plants described, but, by the use of machinery and reducing the hand labor to a minimum, will range from 15 to 16.5 cts. per bushel.

Apple drying, J. Farrell (Jour. Dept. Agr. Victoria, 14 (1916), No. 4, pp. 196-211, figs. 13).—These pages contain a general discussion of the subject and a description of the method and apparatus used for this purpose in Victoria, Australia.

Jelly investigations, W. V. Cruess and J. B. McNair (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, pp. 417-421).—The authors have investigated at the California Experiment Station (1) the suitability of various fruits and vegetables for jelly making, (2) yields of jelly from various fruits, (3) clarification of jelly stock, (4) loss of fresh fruit flavor in jelly making by hydrolysis and evaporation and the production of jellies without application of heat, and (5) effect of sugar and acid concentrations on jelly.

Grapes, apples, loganberries, blackberries, lemons, and pomelos were in all cases found to contain sufficient acid and pectin to give satisfactory jellies. Oranges always contained enough pectin, but were often low in acid. When mixed with lemons in the proper proportion, however, they yielded satisfactory jellies. Apricots and cherries in general were not satisfactory because of a deficiency in pectin. Pomegranates and strawberries did not contain enough pectin, although the acidity was sufficient. Peaches, pears, and huckleberries were deficient both in pectin and acid. Figs and citron melons yielded satisfactory products when acidified with citric acid or lemon juice.

Laboratory tests indicated a maximum yield of 392 gal. of jelly per ton of oranges and lemons used in the ratio of two oranges to one lemon. From a ton of loganberries 467 gal. of jelly could be prepared.

Casein and egg albumin were unsatisfactory as clarifying agents for the jelly. Spanish clay in from 10 to 20 per cent suspensions followed by heating to 100° C. yielded satisfactory results.

The loss of fruit flavor in jelly making was found to be due to decomposition by heat and to direct loss by volatilization. The optimum range of acidity for the production of satisfactory jellies was found to be between 0.5 and 1.5 per cent.

To prevent spoilage by molds and yeasts where jellies were inoculated with these organisms a Brix degree of 65 was found necessary. Jellies which re-

tained the aroma and flavor of the fresh fruit were prepared at room temperature by adding enough sugar to the juice from fruits high in pectin to increase the Brix degree to 65. Loganberries and currants were especially adapted to this procedure.

Jellies, preserves, and marmalades, Agnes E. Harris (Fla. State Col. for Women Ext. Bul. 6 (1916), pp. 28, figs. 2).—This bulletin includes suggestions and recipes for the preparation of jellies, marmalades, and preserves.

Preserving at home, EMHY RIESENBERG (Chicago: Rand McNally & Co., 1916, pp. 32).—This small volume briefly discusses the principle of canning and preserving fruit, molds and molding, sterilization, selection of fruit, fruit jars and glasses, utensils for preserving, preparing fruit for all kinds of preserving, sealing and storing fruits, and keeping fruit clear, and gives recipes for canning fruit and vegetables and preparing jam and preserves, jellies and marmalades, sweet pickled fruits, beverages, homemade pickles, and condiments.

Proceedings of the thirty-first annual convention of the Association of Official Agricultural Chemists, 1914 (Jour. Assoc. Off. Agr. Chem., 1 (1915), No. 3, pp. IV+353-529; 1 (1916), No. 4, pt. 1, pp. 531-599; 2 (1916), No. 1, pt. 1, pp. 91).—This is a detailed report of the proceedings of the convention held at Washington, D. C., November 16-18, 1914, previously noted (E. S. R., 32, p. 294).

METEOROLOGY.

Monthly Weather Review (U. S. Mo. Weather Rev., 44 (1916), Nos. 3, pp. 111-175, pls. 21, figs. 16; 4, pp. 177-242, pls. 10, figs. 12).—In addition to weather forecasts, river and flood observations, and seismological reports for March and April, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during March and April, 1916; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 3.—Convection in the Upper Regions of the Sun's Atmosphere, by F. Henroteau; Seesaw of Pressure, Temperature, and Wind Velocity Between Weddell Sea and Ross Sea, by R. C. Mossmann; Atmospheric Pollution in English and Scottish Towns, by J. B. C. Kershaw (see p. 420); Atmospheric Pollution, by W. P. Wynne (see p. 420); Some Problems of Atmospheric Electricity, by G. C. Simpson; Rainfall Data of Berkeley, Cal. (illus.), by W. G. Reed (E. S. R., 35, p. 116); Distribution of Cyclonic Precipitation, by T. Terada; On Pressure-change Charts (illus.), by E. H. Bowie; Fire Weather Warnings, by H. E. Williams; River-stage Forecasts for the Arkansas River, Dardanelle to Pine Bluff, Ark. (illus.), by H. W. Smith; Disappearance of Snow in the High Sierra Nevada of California, by A. J. Henry; Southern Appalachian Earthquake of February 21, 1916 (illus.), by W. J. Humphreys; and Observations of an Earthquake in a Telescope, by W. P. Hoge.

No. 4.—Total Radiation Received on a Horizontal Surface from the Sun and Sky at Madison, Wis., April, 1911, to March, 1916, by H. H. Kimball and E. R. Miller; Local Circulation of the Atmosphere (illus.), by W. H. Dines; The Planetary System of Convection (illus.), by W. R. Blair; The Average Internal Curve and Its Application to Meteorological Phenomena (illus.), by W. J. Spillman, H. R. Tolley, and W. G. Reed; A Correlation Between the Rainfall of North and South America (illus.), by H. H. Clayton; Report of the Meteorological Station at Berkeley, Cal., 1914 (illus.), by W. G. Reed; A Centigrade Thermometer Scale Preferred; Marcellus Hartley Memorial Medal, 1916; Use of "Indian Summer" in 1778? Need for Pan American

Meteorological Cooperation; Symons Memorial Medal, 1912; Dates of Opening of Navigation through Lake Pepin, 1861–1916; and Snow Surveys in City Creek Canyon, Utah, 1914–1916 (illus.), by A. H. Thiessen.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander, D. Potter, and J. S. Sims (Massachusetts Sta. Met. Buls. 329-330 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1916, are presented. The data are briefly discussed in general notes on the weather of each month.

[Amount and composition of rainfall at Georgetown, Demerara, 1910–1914], J. B. Harrison (*Rpt. Dept. Sei. and Agr. Brit. Guiana, 1914–15, pp. 38–40, App. I, p. 6*).—Monthly and annual averages of the amount and composition (chlorin, nitrogen as ammonia, and nitrogen as nitrates) of rainfall are shown for 25 years—1890–1915.

"In round figures the mean annual rainfall during the 25 years . . . was 98 in. The average rain water contained per liter of water at 84° F. 5.428 mg. of chlorin, 0.0315 mg. of nitrogen in ammonia salts, and 0.0705 mg. of nitrogen in nitrates. During the 25 years the monthly ranges of variation in the constituents of the rain have been very wide, chlorin ranging from 1.77 to 42.552, nitrogen in ammonia from 0 to 1.275, and nitrogen in nitrates from 0 to 0.823 mg. per liter of water at 84°." The average annual rainfall per acre during the period was 97,611 tons, "containing chlorin equivalent to 203 lbs. of common salt and 2.6 lbs. of combined nitrogen in the forms of nitrates and of ammonia."

Atmospheric pollution, W. P. WYNNE (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1915, p. 388; Nature [London], 96 (1915), No. 2407, pp. 442-444, figs. 3; Sci. Abs., Sect. A-Phys., 19 (1916), No. 218, p. 55; U. S. Mo. Weather Rev., 44 (1916), No. 3, p. 114).—This is an abstract of a paper read at the Manchester meeting of the British Association for the Advancement of Science, 1915, based upon monthly results of chemical examinations of rain water collected at four places in Sheffield. The records cover the period from July, 1914, to June, 1915. The results show certain discrepancies which lead to the conclusion "that the method of measurement usually adopted does not afford a reliable indication of the real degree of atmospheric pollution, and that better results might be obtained if a feasible method could be devised for drawing air continuously through water and measuring the amount of the impurities extracted in this way."

The character and extent of atmospheric pollution in English and Scotch towns, J. B. C. Kershaw (Engineer [London], 120 (1915), No. 3125, pp. 473-475, figs. 2; Metallurg. and Chem. Engin., 13 (1915), No. 16, pp. 967-971, figs. 6; abs. in Sci. Abs., Sect. A-Phys., 19 (1916), No. 217, p. 6; U. S. Mo. Weather Rev., 44 (1916), No. 3, p. 114).—This article summarizes and discusses the results of observations on atmospheric pollution in ten English and six Scottish towns during the winter months, October to March, of 1914-15.

It is shown that the dust fall for the English towns during the six months varied from 532 tons per square mile for Oldham to 32 lbs. per square mile for Malvern. The dust deposits were found to consist chiefly of tar, solid carbonaceous particles, and ash, the relative proportions of these not varying widely in the different towns. In the Oldham dust the proportions were 1.5 per cent of tar, 29 of carbonaceous matter, and 69 of ash. As a general rule the percentage of ash has been found to be highest and of tar and soot lowest in manufacturing districts. The observations in the Scottish towns were less complete and are not strictly comparable with those of the English towns. It is claimed that Oldham with a winter soot- and dust-fall at the rate of 1,064 tons per square mile per annum is comparable with Pittsburgh, which

has been reported to have an average fall of 1,031 tons per square mile per

The connection between sunlight, pure air, and health is discussed, attention being called especially to the screening effect of dust-polluted air. Experiments made at Manchester are cited to show that "on a sunny day no less than 12 per cent of the sunlight is cut off in the last 100 ft. of the atmosphere."

International catalogue of scientific literature. F—Meteorology (Internat. Cat. Sci. Lit., 13 (1916), pp. VIII+137).—"The literature indexed is mainly that of 1913, but includes those portions of the literature of 1901-1912 in regard to which the index slips were received by the Central Bureau too late for inclusion in the previous volumes." The sections on the relation of climate to agriculture, forestry, and geography and geology, and on phenology contain some 73 references having more or less direct bearing upon agricultural production.

SOILS—FERTILIZERS.

The soil and its cultivation, P. DIFFLOTH (Le Sol et les Labours. Paris: J. B. Baillière and Sons, 1916, 4. ed., rev. and enl., pp. 572, figs. 204).—This is the fourth revised and enlarged edition of this book (E. S. R., 18, p. 316). It is divided into four main parts, as follows: Agrology, soil cultivation, soil improvement, and reclamation of waste soils.

Soil survey of Clay County, Georgia, W. G. SMITH and N. M. KIRK (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 46, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture and issued May 31, 1916, deals with the soils of an area of 133,760 acres lying within the Coastal Plain province in southwestern Georgia. The topography is generally level or gently rolling with deep, narrow valleys along the streams. "The drainage system is quite complete, reaching into every part of the county, although the streams are still actively cutting."

"The soils of the county are comprised broadly in two divisions or soil provinces, (1) the Coastal Plain soils, or soils of the uplands, and (2) the alluvial soils, consisting of (a) the stream terrace soils and (b) stream bottom soils. The Coastal Plain division includes unconsolidated old sedimentary materials—beds of gravel, sand, clay, and sandy clay—and still older (underlying) beds of consolidated material, chiefly limestone."

Including meadow and rough gullied land, 26 soil types of 13 series are mapped, of which the Norfolk fine sand is the most extensive, covering 21.4 per cent of the area. "There are no soils of sufficient extent or agricultural value to dominate the agriculture of the region."

Soil survey of Turner County, Georgia, E. C. Hall and D. D. Long (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 28, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture and issued June 3, 1916, deals with the soils of a well-drained area of 177,920 acres in south-central Georgia, the topography of which ranges from undulating to rolling. The soils of the county belong in the Coastal Plain and river flood plains soil provinces and are of sedimentary and alluvial origin. Including swamp, 12 soil types of 7 series are mapped, of which the Tifton, Norfolk, and Plummer sandy loams occupy 31.3, 30.4, and 17.6 per cent of the area, respectively.

Winnebago County soils, C. G. Hopkins, J. G. Mosier, E. Van Alstine, and F. W. Garrett (*Illinois Sta. Soil Rpt. 12* (1916), pp. 76, pls. 2, figs. 7).—This is the twelfth of the Illinois county soil reports.

Winnebago County is located in northern Illinois in the Iowan and pre-Iowan glaciations and is covered with a deposit of drift, loess, and alluvial material. The soils of the county are divided as follows: (1) Upland prairie soils, rich in organic matter. These were covered originally with prairie grasses, the partially decayed roots of which have been the source of the organic matter; (2) upland timber soils, including practically all of the upland that was formerly covered with forests; (3) residual soils, including stony loam and rock outcrop; (4) terrace soils, which include bench lands or second bottom lands; (5) late swamp and bottom land soils, which include the overflow lands or present flood plains along the streams and other poorly drained lands." Of these the brown silt loam and brown sandy loam of the upland prairie soils cover 21.35 and 19.1 per cent of the area, respectively, while the yellow-gray silt loam upland timber soil covers 16.13 per cent. "The most significant facts revealed by the investigation of the Winnebago County soils are the lack of limestone and the low content of phosphorus, or nitrogen, or both, in the most common prairie and timber types."

Soil survey of Webster County, Iowa, J. O. Veatch and F. B. Howe (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 44, fig. 1, map 1).—This survey, made in cooperation with the Iowa Experiment Station and issued June 1, 1916, deals with the soils of an area of 456,960 acres in central Iowa, the topography of which is level to very gently undulating without marked relief. A large part of the area is imperfectly drained. "The county lies in that part of the State covered by the last great ice invasion of the Pleistocene period."

The soils are mainly of glacial origin and are prevailingly black. Including peat and muck, eleven soil types of six series are mapped, of which the Fargo loam, Carrington loam, and Fargo clay loam cover 46.6, 23, and 22.1 per cent of the area, respectively.

Soil survey of Jefferson Davis County, Mississippi, T. M. Bushnell and L. V. Davis (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 27, fig. 1, map 1).—This survey, made in cooperation with the State of Mississippi and issued June 8, 1916, deals with the soils of an area of 259,840 acres in southern Mississippi lying entirely within the Coastal Plain. "The topography is prevailingly rolling but seldom too steep for cultivation. Drainage is well established." The upland soils comprise 84 per cent of the area. Fifteen soil types of nine series are mapped, of which the Ruston fine sandy loam covers 52.3 per cent of the area.

Soil survey of Pettis County, Missouri, H. H. Krusekoff and R. F. Rogers (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 41, fig. 1, map 1).—This survey, made in cooperation with the Missouri Experiment Station and issued June 6, 1916, deals with the soils of an area of 432,000 acres in west-central Missouri. "In general, the topography is smooth to gently rolling, with rough areas in the limestone region in the northeastern part of the county."

The soils of the county are "silt loams, containing relatively little sand or clay. They are usually mellow or are easily made so with proper treatment. They are well drained and are moderately early and warm. The subsoils are universally heavier than the surface material which makes the various types generally retentive of moisture. As in most prairie regions, the soils originally had a high content of organic matter, but continuous cropping has reduced this to a large extent." Including rough stony land, 22 soil types of 14 series are mapped, of which the Oswego and Summit silt loams cover 24.9 and 20.8 per cent of the area respectively.

Soil survey of Chautauqua County, New York, T. M. Morrison, C. C. Engle, and G. L. Fuller (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 60, fig. 1, map 1).—This survey, made in cooperation with the New York State College of Agriculture and issued May 22, 1916, deals with the soils of an area of 684,160 acres in southwestern New York which comprises a lake plain and rolling to hilly upland. "The soils have all been derived from glacial débris, originating largely from the sandstone and shales of the region, but with admixture of some foreign material brought in by the ice." Including muck, meadow, and rough stony land, 26 soil types of 9 series are mapped, of which the Volusia silt loam covers 58.1 per cent and the Wooster silt loam 10.2 per cent of the area.

Soil survey of Lincoln County, North Carolina, R. T. A. BURKE and L. L. BRINKLEY (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 33, ftg. 1, map 1).—This survey, made in cooperation with the North Carolina Department of Agriculture and issued May 19, 1916, deals with the soils of a well-drained area of 195,200 acres in the Piedmont Plateau section in southwestern North Carolina, the surface of which ranges from almost level or gently rolling to rolling or broken. The soils are of residual and alluvial origin. Eleven soil types of 5 series are mapped, of which the Cecil clay loam and fine sandy loam cover 42.8 and 12.9 per cent of the area, respectively, and the Louisa gravelly loam and Cecil sandy loam 12.3 and 11.7 per cent, respectively.

The availability of nutrient salts, A. G. McCall (Jour. Amer. Soc. Agron., 8 (1916), No. 1, pp. 47-50).—A comparison of the results of winter wheat cultures in sand, receiving a nutritive solution and the osmotic concentration of which was 1.75 atmospheres, with those obtained in 3 salt nutritive solution cultures led to the conclusions "(1) that the concentration of the nonadsorbed solution in the sand is markedly lower than that of the solution which was added, (2) that the adsorbed salts are either nonavailable or are very greatly retarded in their participation in the growth process of the plant, and (3) that for this particular concentration the ratio of magnesium to calcium ions in the optimum nutritive solution is materially changed by the adsorption process."

The action of chlorids on soil and plant, E. HASELHOFF (Fühling's Landw. Ztg., 64 (1915), No. 19-20, pp. 478-508).—The author reviews work by himself and others on the influence of chlorids, especially sodium and magnesium chlorids, on seed germination, growing plants, the physical and chemical composition of soil, and the productiveness of soil.

It is concluded that plant growth may be inhibited by a solution of 5 gm. of sodium chlorid to 1 liter of water and that the solution is injurious in a concentration as low as 0.5 gm. per liter of water. Owing to the variable influence of different types and composition of soil and plant and of climate, it is thought that no general limiting concentrations can be specified. Similar conclusions are drawn with reference to the influence of magnesium chlorid solutions on plant growth, except that it is thought the permissible concentration may be higher than that of sodium chlorid.

It is further concluded that sodium and magnesium chlorid solutions have practically the same influence on the chemical composition of the soil as do calcium and potassium chlorids, in that the soil absorbs the base of the chlorid so that in the case of magnesium chlorid an injurious excess of magnesia may gradually accumulate in the soil. The injurious influence of chlorids on the physical composition of soil is considered to be especially marked on heavy loam and clay soils and more on meadow than on cultivated soil. No limiting concentrations of chlorid solutions for this purpose can be given.

While results with reference to soil productiveness do not in all cases agree, it is considered evident that the injurious action of chlorid solutions on soil productiveness and on crop yield takes place gradually.

Circulation of manganese in natural waters, V. VINCENT (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 7, pp. 259-261; abs. in Rev. Sci. [Paris], 54 (1916), I, No. 5, p. 158).—Experiments with soil water from natural soils and soils treated with mineral fertilizers are reported, the results of which are taken to indicate that manganese is dissolved in the presence of carbon dioxid and that a bicarbonate analogous to calcium bicarbonate is formed which exists only in solution in soil water. The formula for this is given as MnH₂- $(CO_3)_2$.

It was found that natural mineralized soil waters contained more manganese than ordinary soil water, which is taken to indicate that the use of mineral fertilizers tends to increase the solubility of manganese in soils.

A comparative study of the effect of cumarin and vanillin on wheat grown in soil, sand, and water cultures, J. Davidson (Jour. Amer. Soc. Agron., 7 (1915), Nos. 4, pp. 145-158; 5, pp. 221-238).—The results of work by others bearing on the subject are reviewed and analyzed. Pot experiments conducted at Cornell University are reported, the purpose of which was to determine the effect of cumarin and vanillin on wheat in clay loam soil, water, and quartz.

The soil culture experiments consisted of six series, (1) without additional treatment, (2) with lime, (3) with nitrogen, (4) with phosphoric acid, (5) with potash, and (6) with a complete fertilizer. "The concentrations of 600 parts per million of cumarin and of 3,000 parts per million of vanillin, figured on the basis of the total moisture content of the soil, depressed to some extent the yield of wheat grown to maturity in pots. There are indications, however, that the effect was rather on the soil than on the plant. The addition of small quantities of soil to water cultures entirely destroyed the toxic effects of cumarin, while it did not affect the action of vanillin. . . . In quartz cultures cumarin proved to be as toxic as in water cultures, while vanillin behaved approximately the same way as in the soil. Vanillin is evidently toxic only in a liquid medium when it is applied in mass, but not when it is distributed as films over quartz grains or soil particles. The ameliorating effect of phosphoric acid on the action of cumarin (E. S. R., 26, p. 224) would not seem to be due to its antagonistic behavior with reference to that toxin, since it did not behave in the same way in a balanced solution. . . . behavior of toxic substances is so different in the soil than in water cultures, that one is hardly justified in drawing conclusions from results obtained with water cultures as to what might take place under actual field conditions."

Nitrification, E. R. ALLEN (Mo. Bul. Ohio Sta., 1 (1916), No. 5, pp. 153, 154).—In a brief review of the relations of nitrification in soils to crop production, it is stated that in studies made on plats of the station there appeared to be a very close relation between crop production and nitrification in samples taken from continuous culture plats. "In those taken from the barnyard manure series in the three-year rotation consisting of corn, wheat, and clover there was no consistent relation. The results in the one case were just as striking as in the other. This indicates that the factors which limit crop production in the continuous culture plats are not the same as those which exert a controlling influence in the barnyard manure series."

Recent investigations on the production of plant food in the soil, II, E. J. Russell (*Jour. Roy. Hort. Soc.*, 41 (1915), No. 2, pp. 188–199, figs. 5).—This article deals further (E. S. R., 35, p. 322) with the decomposition of plant residues in the soil as influenced by natural changes indicated by the rate of

oxygen absorption or carbon dioxid production, the rate of ammonification or nitrification, and the changes in bacterial numbers in the soil.

It is pointed out that, as a general rule, soil organisms are dependent upon suitable temperature and water supply, and that they must have food and, in many cases, calcium carbonate, but that "soil bacteria are subject to the operation of some limiting factor quite distinct from temperature, moisture content or food supply." Curves for carbon dioxid and nitrate determination showed a marked similarity except that the increases in nitrate came later, indicating "that the curves both for nitrate and carbon dioxid are in the main production curves."

The author disagrees with the bacterio-toxin theory as developed from laboratory cultures, but produces some evidence showing that the growing plant exerts a depressing effect on soil organisms.

The respective values of organic and inorganic manures, H. E. P. Hodsoll (Jour. Roy. Hort. Soc., 41 (1915), No. 2, pp. 217-226).—Cropping experiments with organic and inorganic manures and comparative studies of their mechanical, chemical, and biological actions in soil are reported. The results led to the conclusion that organic manures should be used as a base to supply humus and thus improve the texture of the soil, enable the obtaining of good tilth and a good seed bed, permit the gradual feeding of the crop, and provide humus to feed bacteria, and that mineral manures should be used as a top-dressing to promote rapid growth and to act as a sterilizer to keep the bacterial flora in balance.

The influence of the time and depth of plowing under of stable and green manure on yield, C. von Seelhorst (Jour. Landw., 63 (1915), No. 3, pp. 233-260, fig. 1).—Field experiments begun in 1905 with rotations of winter barley, beets, oats, beans, rye, potatoes, summer wheat, and peas; and rye, beets, barley, beans, rye, potatoes, barley, and peas are reported. The manures were applied in the fall and spring to beet and potatoes, the green manure being applied usually at the rate of 100 lbs, of vetch and 25 lbs. of horse beans per acre, and the stable manure in amounts equivalent to about 100 lbs. of nitrogen per acre. The depth of plowing was from 5 to 6 in., from 7 to 8 in., and 9 in.

It was found that with beets fall manuring was on the average more favorable than spring manuring. Both manures when used in the fall gave on the average practically the same results regardless of depth of plowing. Shallow plowing in of green manure in the fall gave slightly better results than deep plowing, but no difference was observed with stable manure. When plowed under in the spring green manure gave better results than stable manure when deep plowed, while better results were obtained with stable manure when shallow plowed.

Spring manuring was more favorable to potatoes than fall manuring. Stable manure gave better results than green manure in both fall and spring use, and deep plowing gave better results in both spring and fall than shallow plowing.

With barley following beets the time of manuring of the beet crop had no effect on the barley crop. Shallow plowing under of the manures for beets gave better results for barley in both spring and fall. The after-effect of green manuring in both spring and fall was less than that of stable manure. With barley following potatoes, fall manuring with both manures gave somewhat better results than spring manuring. Deep plowing with one exception gave better results than shallow plowing. The barley crop following potatoes was always somewhat greater than the barley crop following beets.

Spring manuring of potatoes had a somewhat better after-effect on peas than fall manuring. Deep plowing in of both manures for potatoes had a better effect in spring and a poorer effect in fall on the following pea crop than shallow plowing. The after-effect of stable manure was greater for peas than that of green manure. Spring manuring of beets had a better effect on the following bean crop than fall manuring, and deep plowing was better than shallow plowing. Stable manure had a better after-effect on beans than green manure.

Spring manuring of potatoes had a better effect on the rye crop following peas than did fall manuring. Stable manure in this case had a better after-effect than green manure for rye as did also the deep plowing as compared to shallow plowing.

With rye following beans no difference was observed between fall and spring manuring with green manure, but with stable manure the spring manuring had the greater effect. The after-effect of stable manure on rye following beans was better than the after-effect of green manure. Deep plowing in the fall was better in this case also than shallow plowing, while by spring manuring with green manure the reverse was true. With stable manure depth of plowing had no effect.

The rôle of nitrifying bacteria in the decomposition of manure, V. G. SMIRNOV (Zhur. Opytn. Agron., 16 (1915), No. 5, pp. 329-374).—Experiments with artificial manure prepared from horse and cow excrement, sterilized and inoculated with soil nitrifying bacteria under aerobic and anaerobic conditions, are reported.

Under anaerobic conditions nitrogen losses in the form of free nitrogen were considerable from manure inoculated with nitrifying bacteria. Under aerobic conditions the nitrogen losses were small.

It is concluded that the participation of nitrifying bacteria in the decomposition of manure served to reduce the quantity of ammonia nitrogen present. Under anaerobic conditions the losses of ammonia nitrogen increased steadily. This is taken to indicate an increase of combined ammonia and a decrease of free ammonia. As the results did not agree no general conclusions were drawn regarding the transformation of albuminous nitrogen. It was further found that the phosphoric acid content of the manure remained unchanged under both aerobic and anaerobic conditions.

With reference to the conservation of manure and the prevention of nitrogen losses, it is concluded that conditions should be such as to retard the development of nitrifying bacteria and to favor the formation of organic acids which will combine with ammonia.

Green manuring experiments, J. A. VOELCKER (Jour. Roy. Agr. Soc. England, 75 (1914), pp. 295, 296; Woburn Expt. Sta. Rpt. 1914, pp. 12, 13; abs. in Jour. Bd. Agr. [London], 22 (1915), No. 4, p. 353).—It was found in these experiments that rape was the best green manure for wheat, with mustard second, while the crop after tares was the smallest of the three.

The activity and availability of insoluble nitrogen in fertilizers as shown by chemical and vegetation tests, F. R. Pember and B. L. Hartwell (Jour. Indus. and Engin. Chem., 8 (1916), No. 3, pp. 246-251, figs. 2).—Pot culture experiments conducted at the Rhode Island Experiment Station with oats, rye, and millet to determine the availability of the nitrogen of dried blood, tankage, castor pomace, rape meal, sodium nitrate, calcium nitrate, cyanamid, and a number of other nitrogenous fertilizers are reported, together with laboratory tests of the activity of the water-insoluble nitrogen in these fertilizers by the alkaline and neutral permanganate methods.

It was found that "rye and oat plants grown during late fall and early winter did not make as large a growth as those grown after midwinter for the same period under otherwise the same conditions, but the amount of nitrogen removed in the tops of the plants was much the same in both experiments. Although the rye plants did not make as large a growth as the oat plants, the relative growth was much the same with those having like treatment.

"Plants having their nitrogen added in the form of garbage tankage or aluminum nitrid made no larger growth than those to which no nitrogen was added. Nitrogen in water-extracted blood proved just as available to the oat plant as that in the unwashed blood. Plants securing their water-insoluble nitrogen in animal tankage made fully as large a growth as those receiving it in blood. The water-insoluble nitrogen in castor pomace and rape meal proved excellent sources of nitrogen for the growth of oat plants, while Kanona tankage proved to be quite an inferior source of nitrogen. An application of 0.6 gm. nitrogen in cyanamid (165 lbs. of nitrogen per acre) proved toxic to the young plants but they were able to overcome the toxicity and make a fair growth. . . .

"The nitrogen in soot had an availability of 56 compared with that in blood at 80. Nitrogen in oxamid produced plant growth about equal to the average produced by that in blood and in nitrate of soda.

"Lower activities secured by modifications of the neutral permanganate method in general agreed no better with the availabilities than those secured by the unmodified method. Of the 56 fertilizers tested, not only by the oat plant but also by the alkaline and neutral permanganate methods, 24 were found to contain water-insoluble nitrogen having an availability of less than 45 as compared with blood nitrogen at 80. Of these, 13 were actually classed as inferior by having an activity of less than 55 by the alkaline permanganate method, and three more were practically so classed, their activities being only one to two points higher. Two having availabilities of only 54 and 50 were condemned by activities of 51 and 41. None was condemned by the alkaline method which proved to have a high availability. The neutral method, on the basis of activities of less than 80, detected 19 of the 24 inferior ones and three more having availabilities of only 54, 50, and 49, but condemned three with the satisfactory availabilities of 81, 74, and 68. . . .

"About the same percentage of the inferior samples was detected by the two methods, but the neutral method condemned some samples which proved to have satisfactory availabilities according to the vegetation tests. The percentage of the insoluble nitrogen attacked by the potassium permanganate solution agrees much closer with the relative availability by vegetation test, in case of the alkaline than of the neutral method."

Field experiments on the action of new forms of nitrogen, Schneidewind (Mitt. Deut. Landw. Gesell., 31 (1916), No. 2, pp. 16-20).—Field experiments are reported with potatoes on dry sand soil; with potatoes, beets, and rye on damp sand soil; and with sugar beets, oats, winter rye, and summer wheat on humus loess loam soil to compare the fertilizing action of sodium, calcium, ammonium, and urea nitrates; ammonium chlorid and sulphate; urea; and lime nitrogen when added in amounts equivalent to 0.3, 0.45, and 0.6 kg. of nitrogen per 100 square meters.

The results indicate that ammonium chlorid, ammonium nitrate, urea, and urea nitrate were equal in fertilizing action to ammonium sulphate, and the last three in some cases were equal to sodium nitrate. Ammonium nitrate, however, has the disadvantage of being very hygroscopic and explosive. The average fertilizing action of lime nitrogen was somewhat less than that of the other fertilizers. The two types of calcium nitrate were equal in fertilizing

action to sodium nitrate, although the latter is deemed generally preferable as it is more easily stored and used.

The industry and commerce of nitrogenous substances, A. Bertrand (Assoc. Sal. Propaganda Bol. 8 (1915), Sup., pp. XV+155).—This report deals with the sodium nitrate, ammonium sulphate, synthetic nitric acid, cyanamid, synthetic ammonia, and aluminum nitrid industries, with the different processes of manufacture involved in these industries, and with their relative commercial standing.

Experiments with phosphatic manures on green crops (Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 4 (1915), pp. 94-99).—Plat experiments with a number of green crops. including white and brown cowpeas, on an acid soil deficient in phosphoric acid, to determine the relative fertilizing value of a so-called basic phosphate, degelatinized bones, superphosphate, and basic slag showed that in their order the phosphorus fertilizers produced increases in crop yield of 38, 164, 273, and 273 per cent. The basic phosphate was very slow in action and is considered unsuitable for growing green crops on this soil. The bone fertilizer gave rapid results, but was expensive, and its immediate effect for the same price did not compare well with that of superphosphate and basic slag. In the absence of phosphoric acid no increase in crop was obtained from the use of nitrogenous and potassic manures.

A table showing the relative costs of the fertilizers for equal efficiencies is also included.

The solubility of different phosphates and their utilization by oats and buckwheat, T. Pfeiffer, W. Simmermacher, and W. Rathmann (Landw. Vers. Stat., 87 (1915), No. 2-3, pp. 191-214).—Pot-culture experiments with oats and buckwheat and laboratory experiments with dicalcium and tricalcium phospiates and a coral rock phosphate are reported, the purpose of which was to determine the availability of the phosphoric acid of the phosphates to the crops and the relation of its availability to its solubility in water saturated with carbon dioxid. The dicalcium phosphate contained 50.65 per cent phosphoric acid, the tricalcium phosphate 40.75 per cent, and the coral phosphate 39.82 per cent. The last-named phosphate contained 10.78 per cent phosphoric acid soluble in 2 per cent citric acid.

It was found that the solubility of the phosphates as indicated by water saturated with carbon dioxid did not always correspond with the availability of the phosphoric acid as indicated by the cropping experiments. The buckwheat was better able to assimilate phosphoric acid from difficultly soluble phosphates than was oats, this being attributed to the content of organic acids in the root sap.

Experiments on the action of the phosphoric acid in different Thomas meals, Tacke, Gerlach, Schneidewind, Haselhoff, and Eberhaft (Landw. Vers. Stat., 87 (1915), No. 2-3, pp. 89-95, pls. 6).—Reports from five German experiment stations of cropping experiments with 19 different types of Thomas meal are reported, the purpose of which was to determine the relation between the availability of the phosphoric acid in the different meals as indicated by cropping experiments and the availability as determined by the 2 per cent citric-acid method. It is concluded that there is no ground for rejecting the method employing ammonium citrate solution containing 1.4 per cent free citric acid for determining the availability of the phosphoric acid of Thomas meal.

Phosphates and phosphatic marls (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 1, pp. 152-159).—This section of the report contains the results of analyses of 31 samples of Florida phosphates and phosphatic marls.

Idaho phosphate resources, R. N. Bell (Jour. Electricity, 36 (1916), No. 13, pp. 243-246).—The details of the fertilizer resources of Idaho and Montana are discussed with special reference to extensive beds of what is considered high-grade rock phosphate in Idaho.

Investigation of a reported discovery of phosphate in Alberta, H. S. DE SCHMID (Canada Dept. Mines, Mines Branch Bul. 12 (1916), pp. IV+38, pls. 13, fig. 1).—This report deals with the geology, general characteristics, and extent of a phosphate bed near Banff, Alberta.

It was found that the deposit possesses an average thickness of about 12 in. and contains an average of about 43.7 per cent of tricalcium phosphate and 43.3 per cent of insoluble matter, chiefly silica. From the data obtained it is assumed that there are 10 square miles of beds, or 26,137,600 short tons, of phosphate rock. "There are at least two outcrops of the phosphate bed that are conveniently situated as regards accessibility and transportation facilities, the one being about 4 miles from Banff station and the other hardly more than a mile from the railroad. While unsuited to the manufacture of superphosphate by the sulphuric-acid method, owing to the low content of tricalcic phosphate . . . and to the large amount of silica present . . . the Alberta rock would possibly prove suitable for treatment by one of the thermic processes that have lately been proposed to supplant the sulphuric-acid method."

Recent progress of mineralogy in relation to soils: The investigation of potash and phosphate beds, B. Gossner (Forstw. Centbl., n. ser., 38 (1916), Nos. 1, pp. 1-18; 2, pp. 77-84, figs. 6).—This article deals briefly with the mineralogy and geology of the principal known deposits of phosphates and potash salts in the world. A list of nine references to literature bearing on the subject is included.

Conservation of potassium, J. W. Ames (Mo. Bul. Ohio Sta., 1 (1916), No. 5, pp. 155-158).—This article deals with the liberation of the potassium of the soil by the use of fertilizers, lime, and organic matter, and reports the results of analyses made at the station of crop residues and solid and liquid manure with special reference to potash content.

Lime as a soil improver, H. J. DANNFELT (K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 1, pp. 43-57).—This is a discussion of the beneficial influences of lime on the physical and chemical properties of soils, attention being drawn, however, to its injurious action, in excessive amounts, on soil bacteria.

Injury to plant growth by caustic lime, ROTHERT (Jour. Landw., 63 (1915), No. 3, pp. 227-232).—Pot experiments with barley on mild loam soil and a red sand, to determine the limits within which caustic lime may be used on heavy and light soils without injury to plant growth and the influence of caustic lime on nitrate formation in these soils, are reported.

Caustic lime was added to the loam soil in amounts of 0.25, 0.5, and 0.75 per cent and to sand in amounts of 0.05, 0.1, and 0.25 per cent. The growth of barley plants on the loam soil was retarded from the beginning with the largest lime addition, and after a short time with the medium lime addition. In the sand cultures no difference in plant growth was observed in the beginning between limed and unlimed soil. The crop yield in the loam soil was greatly reduced by liming, being smaller the greater the amount of lime added, but in sand was favorably influenced, this being more marked with the smaller amounts of lime added. Liming increased nitrate formation in both sand and loam soils, this usually being greater with the smaller lime additions.

These results are taken to indicate that excessive liming of light sand soils may be injurious owing to the increase and loss of nitrates and the

decrease of humus content, but that this is not so likely to occur in heavier soils.

The sensitiveness of different lupines and other plants to lime, L. HILTNER (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 13 (1915), No. 5, pp. 53-59, flg. 1).—
The author reviews experiments by himself and others, the results of which are taken to indicate that lime chlorosis of lupines and the chlorotic appearances of other kinds of plants which are attributed to an excess of lime in the soil may be obviated by spraying with solutions of iron salts. It is concluded that the sensitiveness of lupines to lime is due to the injurious action of the lime on the nodule bacteria.

Magnesia and plant growth, B. C. Aston (Jour. Agr. [New Zeal.], 11 (1915), No. 6, pp. 493-502, figs. 3).—The work of others bearing on the subject is briefly reviewed, and the rather general results of pot and field experiments on New Zealand soils containing an injurious excess of magnesia are reported.

The results are taken to indicate that "if in a soil the amount of magnesia exceeds that of the lime, judged by means of a strong solution of hydrochloric acid, and such excess be deemed to be injurious, a great number of New Zealand soils, according to analytical records, stand in immediate need of some form of lime from this cause alone. . . . If the excess be judged by a weak acid solution, the number of known soils with an injurious amount of magnesium in them becomes narrowed down to a few localities in the Nelson Province. . . . As to the remedy for excessive magnesia in the soil. . . . in extreme cases land plaster (gypsum or sulphate of lime) or larger dressings of ground limestone (carbonate of lime) should be applied."

[Trials with bacterized peat and magnesium sulphate], J. Dunlop (Midland Agr. and Dairy Col., Rpt. Field Trials Col. Farms, 1915. pp. 53-55).—Tests of bacterized peat used on wheat, hay, and potatoes at the rate of 700 lbs. per acre and of manganese sulphate used on potatoes at the rate of 25 lbs. per acre gave negative results. "Apparently, therefore, little or no help is to be got from either 'humogen' or sulphate of manganese in increasing food production."

[Fertilizer analyses], R. E. Rose and F. T. Wilson (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 1, pp. 53-93).—This section of the report contains actual and guarantied analyses of 422 samples of fertilizers and fertilizing materials offered for sale in Florida during 1915.

Commercial fertilizers: What they contain and their uses, W H. Stroud (Wisconsin Sta. Bul. 265 (1916), pp. 11, fig. 1).—This bulletin discusses the composition, valuation, and use of commercial fertilizers, reports the results of actual and guarantied analyses of 35 samples of licensed fertilizers and fertilizing materials and analyses of 12 samples of unlicensed fertilizers and ground limestone offered for sale in Wisconsin during 1915, and summarizes the State fertilizer law.

Miscellaneous samples, limestones, marls, shells, L. Heimburger (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 1, pp. 159-167).—This section of the report contains the results of analyses of 47 miscellaneous samples of Florida limestones, marls, and shells.

AGRICULTURAL BOTANY.

Pfeffer jubilee volume (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. XVI+832, pls. 11, figs. 64).—This volume, in honor of Wilhelm Pfeffer, commemorates the fiftieth anniversary of his doctorate and the seventieth of his birth. In addition to the articles noted elsewhere in this issue, it contains the following contributions: The Influence of Centrifugal Force on

Plants, by F. M. Andrews; Thiospirillum jenense and its Reaction to Light Stimulus, by J. Buder; Spore Generation and Release by Coprinus sterquilinus, by A. H. R. Buller; The Distribution of Certain Liverworts of the Malay Region, by D. H. Campbell; Physiological Fragments from a Tropical Forest, by F. C. von Faber; Anatomical and Physiological Studies on the Flowers of the Orchid Genera Catasetum and Cycnoches, by H. R. von Guttenberg; Gas Exchange in the Marine Algæ, by R. Harder; Disorganization of the Tapetum Cells in Pollen Sacs of Angiosperms, by H. O. Juel; Growth and Rest of Tropical Trees, by G. Klebs; Nutritive Physiology of Extreme Atmospheric Epiphytes, by R. Lieske; Problems Regarding the Twining of Plants, by H. Miehe; Studies on Prothallia of Ferns with Regard to Imbedded Antheridia and Apogamy, by D. M. A convenient modification of the porometer, R. C. KNIGHT (New Phytol., 14 (1915), No. 6-7, pp. 212-216, fig. 1).—The author describes a form of porometer which he has devised, with a typical experiment illustrating its use. Some advantages are claimed for this form over that used by Darwin and Pertz (E. S. R., 27, p. 222).

On the use of the porometer in stomatal investigation, R. C. Knight (Ann. Bot. [London], 30 (1916), No. 117, pp. 57-76, figs. 7).—This is an account of preliminary experiments carried out looking to discovery of possible sources of error in work done with the porometer above mentioned. These include temporary deformations of the leaf due to pressure differences, the tendency of stomata to close when air is drawn continuously through them, the temporary tendency to close after rough handling, and the disproportionately great resistance offered by intercellular spaces. In the plants investigated there was a considerable similarity in the behavior of the stomata of different leaves, but still more in that of those of the same leaf. Stomata of a mature healthy leaf may open more widely than those of either a very young or very old leaf.

A description of a recording porometer and a note on stomatal behavior during wilting, C. G. P. Laidlaw and R. C. Knight (Ann. Bot [London], 30 (1916), No. 117, pp. 47-56, figs. 3).—The apparatus here described is essentially a continuously acting, self-recording modification of the porometer briefly described in the paper noted above. A constant-pressure aspirator is employed to draw air through the leaf, and the speed of the air stream (inferentially also the relative size of the stomatal apertures) is measured by the rate of flow. The results obtained are said to be very satisfactory, and to show close agreement with the observation of Darwin and Pertz that in case of a leaf detached from the plant the stomata opened temporarily before their final closure, the phenomenon being ascribed to wilting.

The gas exchanges of water plants, H. KNIEP (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festchr., pp. 460-510).—This is a contribution on the method of bubble counting, and the several sections deal with the oxygen content of the bubbles as related to the rapidity of their formation, the effect of water movement on bubble production, the interruption of bubble production by interruptions of the light supply, and a new method of ascertaining the minimum light intensity required for assimilation.

Synthetic processes in plants, II, P. BOYSEN-JENSEN (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 431-446).—Continuing earlier work (E. S. R., 28, p. 127), the experiments described are claimed to have shown that two stages may be distinguished in the germination of peas. In the first of these cane sugar is utilized, partly for growth, partly for respiration. Separated cotyledons show a decrease of cane sugar. In the second stage the

same material is present in the cotyledons as the transferable form of starch. The concentration of cane sugar is greater in the cotyledons than in the embryo and increases in the former when they are separated, decreasing in the latter under that condition. The cotyledons contain only small proportions of reducing sugar.

The mode of formation of cane sugar is not indicated by the results obtained in these experiments. The formation of cane sugar from maltose is considered improbable, but it is thought that starch may be hydrolyzed to monosaccharids, and that this material may then form saccharose. It is considered probable that both monosaccharids and disaccharids may appear as translocable forms of starch.

Some experiments on the influence of temperature on the rate of growth in Pisum sativum, I. Leitch (Ann. Bot. [London], 30 (1916). No. 117, pp. 25-46, pl. 1, figs. 10.—In experiments with P. sativum the author has found that the relation of growth to temperature can be expressed by a uniform curve from -2 to 29° C. Above this point the relation can no longer be expressed as a curve, each higher temperature requiring a different curve to show the rate of growth in successive intervals of time. Between 30 and 40° these are not simple time curves. A well-marked optimum appears to lie between 28 and 30°, and the maximum rate temperature appears to be 30.3°. A bibliography is appended.

Sap ascent, E. B. COPELAND (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 447-459, fig. 1).—Reviewing the literature of the forces concerned in the elevation of sap in plants, the author describes experiments carried out, claiming that living cells are not essential to the ascent of water in stems and that differences in pressure of water columns in plant stems do not necessarily correspond to differences in pressure in tubes containing water columns of the same height.

The cohesion theory of water movement, O. Renner (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 617-667, pl. 1, figs. 4; abs. in Naturwissenschaften, 3 (1915). No. 10, p. 136).—The author has studied the forces and resistances concerned with water movement in plants, more particularly as noted in connection with deformation of the annulus in fern sporangia. Evidence was obtained in the study of water in the cells of the annulus of a degree of tension amounting in extreme cases to 350 atmospheres.

Cohesion and osmosis, C. Steinbrinck (Ber. Deut. Bot. Gesell., 33 (1915), No. 8, pp. 451-460).—This is a review of several contributions bearing upon questions of cohesion and osmosis, giving more particular attention to recent work by Renner as above noted.

The cohesion of water in the annulus of the sporangium in ferns, A. Ursprung (Ber. Deut. Bot. Gesell., 33 (1915), No. 3, pp. 153-162, figs. 2).—The author claims to have found that distilled water in the cells of the sporangial annulus in ferns developed a tension of about 300 atmospheres.

Views of biological adsorption phenomena, F. Czapek (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 84-111).—This is a review of some investigations and opinions since 1803 regarding adsorption and related phenomena, dealing somewhat particularly with the more recent developments concerning phenomena of the colloidal state and cell behavior in connection therewith.

Studies on the entrance of salts into living cells, H. Fitting (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 1-64, figs. 3).—The several divisions of this report deal with the method involved, the rapidity of entrance of potassium nitrate into the cell, the association of this salt with a decrease of permeability to water, the causation of alterations in permeability for this

salt, the permeability relations of other salts, and a discussion of the facts observed.

In leaves of *Rhwo discolor*, plasmolysis was rapid, reaching its maximum in about 15 minutes, and then showing a reversal. Preliminary experiments with other objects are said to indicate that the influence of salts on the permeability of plasma may prove to be more widely prevalent than it is now known to be. No support was found for the view that decrease of permeability is referable to injury of the protoplasm. These experiments are considered to throw light on the nonreversal of plasmolysis as sometimes observed, also to show that the inflow of salts does not necessarily proceed as far as equilibrium of the internal and the external solutions. They are said also not to support the lipoid theory regarding the uptake of nutrient materials.

A bibliography is appended.

Absorption of ions by plants, E. Pantanelli (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 689-733).—The author reports investigations bearing upon the questions of the dependence between uptake of cations and that of anions, changes in chemical reaction of the medium external to the plant following ionization, antagonistic influences of ions as affecting uptake, influence of concentration, curves of uptake, and mechanics of salt absorption.

It is stated that the uptake of a salt by living plasma is a phenomenon of adsorption. Ions of salts are absorbed separately and not in salt molecules as wholes, cation and anion being generally absorbed in different proportions. Ion adsorption is independent of water adsorption. Its rapidity differs with the nature of the ions involved and with time, but not uniformly. Above a certain concentration, all ions lead to an increase of specific permeability, thus opening up a new field to adsorption. Evidence has been obtained of the separateness of extrapermeability and intrapermeability in this connection. Slight narcosis decreases uptake of most, but not all, ions. Apparently, undetermined physiological factors are operative. Slight narcosis may oppose uptake of nutritive ions and may favor that of injurious ones.

A bibliography is appended.

Concerning the comparative rapidity of absorption of anions and cations by plants, E. Bobko and E. N. Sinskafa (Iz Rezul't. Veget. Opytor Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 448-455).—Barley, lupine, and pumpkin were grown in the presence of potassium, ammonium, magnesium, and calcium sulphates. In another test barley alone was grown with potassium, sodium, ammonium, and calcium chlorids.

With sulphates it was definitely found that the ions are absorbed independently, although no such pronounced deviation from the original ratio as reported by Pantanelli was observed between the absorption of the cation and the anion. The same experiment showed that there is a connection between the absorption of certain ions and changes in alkalinity, but no explanation of this phenomenon is advanced. With chlorids, absorption of anions by barley prevailed over absorption of cations in all cases except that of ammonium chlorid.

On the question of the equivalent absorption of anions and cations by plants, G. I. RITMAN (RITTMAN) (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 505-518).—These experiments were carried out with peas to determine the relative intensity of absorption of the anions and cations of calcium salts. The plants were grown in the dark as well as in the light and examined at various stages of development.

It was found that in all cases, the anions and the cations of the chlorids and the sulphates were absorbed at the same rate, but with a tendency to a

somewhat greater assimilation of the calcium. On the other hand, the anions of the nitrates and the phosphates were absorbed in considerably larger amounts than the calcium ions. The difference in the amount of absorbed anions and cations in these cases was so large that in no way could it be accounted for as a possible experimental error.

Effect of osmotic pressure in nutrient solutions on plant growth, A. A. Stol'gane (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 514-550, pl. 1).—The object of the author's experiments was to determine the effect of the osmotic pressure in nutrient solutions on the general development of plants and on their absorption of nitrogen. Flax and barley were grown in sand and water cultures to which various combinations of nutrient solutions were added containing ammonium nitrate as well as sodium chlorid, potassium chlorid, magnesium sulphate, potassium sulphate, and sodium sulphate.

It was found that the plants can resist only a comparatively low osmotic pressure, which, however, when not exceeding two atmospheres, as was the case with sodium chlorid, has even a stimulating effect upon the growth. Growth was retarded by increased osmotic pressure and all the vegetative processes may be checked entirely if the pressure becomes much higher than two atmospheres. The percentage of nitrogen increased with increase of pressure, but its total amount as shown in the yield was diminished except in those cases where the osmotic pressure was comparatively low.

Stimulants of plant growth, F. V. CHIRIKOV (T. TSCHIRIKOW) (*Iz Result. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.*), 9 (1913), pp. 431-435).—This work is a continuation of experiments of the previous year, potassium permanganate, manganese chlorid, molybdic acid, sodium tungstate, uranium nitrate, and iron sulphate being tested as stimulants of plant growth with Persian wheat, Swedish wheat, buckwheat, and peas grown in sand cultures.

With wheat it was found that all the stimulants gave more or less positive results, while with the other plants the results were variable. When two stimulants were present together in the same culture, their combined effect represented very closely the aggregate action of the two chemicals taken separately. Uranium nitrate and sodium tungstate increased the quantity of seeds in peas. The largest general increase of yield for wheat was obtained with manganese chlorid, and for peas with uranium nitrate.

The metabolism of nitrogenous substances in etiolated shoots of barley nourished on ammonium salts, A. I. SMENOV (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 470-504).—Experiments carried out with carbamid, ammonium nitrate, and ammonium chlorid, the ammonium nitrate and chlorid being used with and without the addition of calcium carbonate and calcium sulphate, demonstrated that seedlings of barley absorb the nitrogen of the ammonium salts very energetically during the first days of growth, showing also an increased activity in the formation of asparagin. Later on the rate of absorption gradually decreased, but this was not found to be due to the lessening of osmotic pressure in the solutions.

Calcium salts influenced the assimilation of nitrogen from ammonium salts and stimulated the formation of asparagin, as well as the splitting of proteins. The nitrogen of the nitrates was absorbed with equal energy.

Assimilation of nitrogen from ammonium salts and accumulation of ammonium salts in the tissues were in reverse proportion. This fact is connected with the consumption of carbohydrates and is analogous to the behavior of etiolated seedlings of lupines, plants poor in carbohydrates.

Absorption of negative ions by seedlings of barley was found to take place only during the first few days of the experiment.

Concerning the relation of etiolated shoots of maize and lupine to ammonium salts and nitrates, D. N. Prânishnikov (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 559-565).—This is a brief account of some unpublished experiments conducted at the Moscow Agricultural Institute of Russia by the late S. I. Kalinkin,

These experiments show that ammonium salts as well as nitrates serve as a source of nitrogen in etiolated maize plants. However, more nitrogen is absorbed from ammonium salts than from nitrates, and, as regards the latter, calcium nitrate appears to be a better source of nitrogen than sodium nitrate. With lupines, ammonium chlorid caused a loss of nitrogen, a lower asparagin content, and a higher ammonium content. Nitrates did not bring about so great an absorption of nitrogen or formation of proteins in lupines as in maize.

Stereochemistry and the biological action of ammonium compounds, F. Plate (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 23 (1914), II, No. 7, pp. 292–296).—The author thinks that the diverse action of the chlorid and the nitrate of ammonia, as shown by the behavior of plants in nutritive solutions, is due to differences in the stereochemistry of these compounds, which are discussed.

The action of ammonium compounds on Avena sativa, F. PLATE (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 24 (1915), I, No. 2, pp. 146-148).—The author takes occasion to point out and correct certain typographical errors said to have passed undetected in the contribution above noted and to indicate the methods employed in the further study of this subject as now in progress.

The direct assimilation of atmospheric nitrogen by plants, EVA MAMELI and G. POLLACCI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 9, pp. 966-971).—This is mainly a discussion of reports and views of the authors (E. S. R., 25, p. 633; 31, p. 223) and of others noting some probable causes of error or insufficiency in work on this subject.

The question of absorption and utilization of chlorids by plants, A. S. Kablukov (Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 551-558).—In these experiments lupine and barley seedlings were transferred to solutions of magnesium, calcium, ammonium, and potassium chlorids. The anion was absorbed in a much larger amount than the cation only in the case of barley grown with sodium chlorid. In all the remaining cases the absorption of the anions and cations was practically equivalent.

Magnesium in chlorotic or discolored plants, Eva Mameli (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 3, pp. 262-267).—Comparative analysis is said to show a smaller percentage of magnesium in chlorotic or discolored leaves or leaf parts than in normal portions of the same plant. Willstätter's studies in this connection, previously noted by the author (E. S. R., 29, p. 323), are again discussed.

The influence of phosphorus and magnesium on chlorophyll formation, Eva Mameli (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 7, pp. 755-760).—This is largely a review of the work and views of various investigators on this subject as bearing upon the work of the author, noted above or set forth in the present report, which is made on studies carried out with Zea mays and Polygonum fagopyrum in a nutritive solution lacking magnesium. The plants were etiolated or pale green and the chloroplasts were abnormal in form as well as in color, while plants similarly treated but deprived of phosphorus were normal in these respects.

The influence of the pyrrolic acid nucleus on the formation of chlorophyll. G. Pollacci and B. Oddo (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 1, pp. 37-39).—It is stated that in case of

Zea mays, germinated in a nutritive medium free from iron but containing a very small proportion of magnesium pyrrolic carbonate, the plantlets when 20 days old were well developed and normally green while the control, which lacked this magnesium compound, remained backward and showed only a very small amount of green, which was confined to the first two leaves.

The effect of the concentration of the nutrient solution on the growth of barley and wheat in water cultures, Winifred E. Brenchley (Ann. Bot. [London], 30 (1916), No. 117, pp. 77-90, pl. 1, figs. 4).—It is stated that in case of barley and wheat grown in nutrient solutions under favorable conditions the concentration influences greatly the rate and total of growth even when the balance of the solution approximates a constant level. Starvation effects were noted at much higher concentrations than reported in this connection by some observers. The action of different high concentrations of constant balance has not been determined and it is considered uncertain whether there exists a distinct optimum or a range of equally beneficial concentrations.

The influence of strong Röntgen rays on the germination and growth of higher plants, M. Koernicke (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 416-430, figs. 4).—Giving an account of the effects of X-rays of varying strength on different plants, the author states that these rays parallel other rays and various bodies in solution in their biological influences, inasmuch as heavier dosage checks while lighter dosage favors the development of the plants and the activity of the process which normally take place within them.

Smcke as a means of shortening winter rest, H. Molisch (Umschau, 20 (1916), No. 12, pp. 230-233, figs. 5).—Smoke of tobacco, paper, or sawdust gave essentially the same result in hastening the resumption of activity after the winter rest period in case of several common plants exposed thereto for one or two days. The manner in which these results are produced was not discovered.

Botanical diagnosis of smoke injury in forests, F. W. Neger (Naturwissenschaften, 4 (1916), No. 7, pp. 85-90, figs. 4).—Following up his previous work (E. S. R., 35, p. 243) by alleging a degree of unreliability of certain phenomena as criteria for smoke injury to forest vegetation, the author states that it is inevitable that smoke effects should resemble more or less those of drought and frost, since each results in the killing of the plasma of the assimilating cells, causing a sudden loss of water and the subsequent drying of these parts.

Anomalies in Beta vulgaris, I, II, O. Munerati and T. V. Zapparoli (Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 4 (1915), I, Nos. 11, pp. 1150-1158, figs. 12; 12, pp. 1236-1239, figs. 3).—This discussion of anomalies of beets includes cotyledonary leaves, fasciation, ascidiform leaf structure, neurochorisis affecting the median nerve, trumpet formation of leaves, filiform growth of leaves, cortical melanism, degeneration of roots, and other peculiarities.

Studies on the phylogeny of Nicotiana tabacum, G. E. Anastasia (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 11, pp. 1146-1150).—Giving an account of studies carried out subsequently to those previously reported (E. S. R., 18, p. 635), the author holds that N. tabacum was originally derived from a hybridization of the two forms N. rustica and N. petunioides.

The floral biology of the peach, C. Campbell (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 1, pp. 68-73, figs. 2).—This is a discussion of the floral characters of the peach considered as being not only of biological and systematic, but also of agricultural, importance.

The floral biology of the almond, C. Campbell (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 3, pp. 256-261, figs. 9).—This is a discussion of anomalies in the floral parts of the almond, pointing to the necessity for study bearing upon the attainment of certainty and regularity in the output.

Chimeras and graft hybrids, J. Buder (Naturwissenschaften, 3 (1915), Nos. 1. pp. 6-9, figs. 4; 2, pp. 23-25, figs. 3; 3, pp. 33-36; abs. in Bot. Centbl., 129 (1915), No. 2, p. 20).—The author discusses the conditions for the production of graft hybrids and the necessary relations of the cells of the symbionts to each other and to the growing point, which are described in typical forms.

FIELD CROPS.

Comparative study of the root systems and leaf areas of corn and the sorghums, E. C. Miller (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 9, pp. 311-332, pls. 7, figs. 3).—The methods and results of experiments conducted at the Garden City, Kans., substation of the Kansas Experiment Station, to determine the fundamental characteristics of sorghum plants enabling them to withstand severe climatic conditions better than the corn plant, are described. The data secured, together with a summary of climatic conditions, are given in tables and discussed.

In all stages of growth the primary root systems were found equally extensive, but the secondary roots of the sorghum plants as compared with those of corn were twice as numerous per unit of primary root. Both primary and secondary roots of the sorghums were found to be more fibrous than those of corn. A study of the weight of the dry matter of the aerial portions and of the roots of mature plants showed an average ratio of the dry weight of the grain, stem, and leaves of standard Kafir to the dry weight of the roots of 15:1 and 14.9:1 in 1914 and 1915, respectively, while the dry weight of the stem and leaves of the same plants was on the average 10.9 times that of the root weight in 1914, and 10.1 times the root weight in 1915. The average ratio of the dry weight of the aerial portions of dwarf milo maize to the weight of the roots was found to be 15.7:1 in 1914 and 15:1 in 1915. The weight of the stem and leaves of the same plants was 9.6 times and 8 times, respectively, the weight of the roots for the two years. The weight of the stem and leaves of Pride of Saline corn was 9.6 times the root weight in 1914 and 7.8 times the weight of the root system in 1915. The aerial parts of dwarf Blackhull Kafir corn in 1915 showed a weight of 15.7 times that of the roots, and the weight of the stem and leaves 8.9 times the weight of the roots. The results of experiments regarding soil moisture content and depth of root penetration seemed to show that under the existing conditions very little, if any, depletion of soil moisture took place below the depth of root penetration.

The leaf area of the corn plant at all stages of its growth was found to be approximately twice as great as that of Dwarf Milo maize and never less than 1.5 times that of Blackhull Kafir corn. It is pointed out that the sorghums would have the advantage over the corn plant under any climatic condition tending to bring about a loss of water from the plants. The two sorghums as compared to the corn plant have only one-half the leaf surface exposed for the evaporation of water, and also have a root system which, judging from the number of secondary roots, would be twice as efficient in the absorption of soil moisture.

Contribution to the question of spacing and feeding the individual plant in plant breeding, R. Leidner (Ztschr. Pflanzenzücht., 3 (1915), No. 3. pp. 353-370).—This article discusses the views of different authorities on plant

breeding with reference to spacing plants in experimental and practical plant breeding, giving special attention to the recommendation of Mitscherlich that each plant be given sufficient space to enable a person to walk around it and to treat it frequently with nutrient solution. The author concludes that this plan does not meet practical requirements and expresses the belief that the practical plant breeder should be advised to adhere to the customary spacing in pedigree and selection work.

Rotations and tillage methods in western Nebraska, W. P. SNYDER and W. M. OSBORN (Nebraska Sta. Bul. 155 (1916), pp. 6-48, figs. 6; pop. ed. (1915), pp. 21, fig. 1).—This bulletin is a report on plat experiments begun in 1906 at the North Platte Substation in cooperation with the Bureau of Plant Industry of the U. S. Department of Agriculture for the purpose of testing various rotations, crop sequences, and methods of tillage in the production of corn, spring wheat, oats, barley, and sorghum hay. The deductions presented are based on the average results of eight years' work.

The weather conditions of the season are recognized as the greatest factor in controlling yields. The seasonal precipitation was found to have a much greater influence on the crop production than methods of seed-bed preparation, crop sequence, or the use of manure. During favorable seasons profitable crops were produced by all methods under test and during unfavorable seasons profitable crops were not produced by any method. The system of alternate cropping and summer tillage failed to overcome severe drought conditions, and was less profitable in the production of corn and spring grain than ordinary methods of production. In some unfavorable years, however, this method gave a large increase in yields over common practices.

In considering the average yearly profit or loss per acre for the eight years, it is shown that corn grown on summer-tilled land gave a loss of 3 cts. as against a profit of \$3.65 for corn grown continuously. Spring wheat gave a profit of \$2.11 when grown on summer-tilled land and a profit of \$2.28 or \$3.06 on land growing wheat continuously. Oats gave a loss of \$2.29 per acre on summer-tiled land while on land continuously cropped the loss was small. Barley gave a loss of \$2.08 per acre on summer-tilled land and a small profit on land continuously cropped.

The results of the eight years further indicated that from the standpoint of yield or profit it mattered but little whether the land was spring plowed or fall plowed for fall or spring grains. The difference in the yield of spring wheat on land that grew spring grain or corn the previous year was not marked during any season. Almost every year corn following corn yielded more than corn following small grain. The average annual difference for the eight years is reported at 5 bu. per acre in favor of land growing corn the preceding season. The yields of spring wheat and oats following sorghum grown for forage were not much different from the yields of the same crops following corn or spring grain. In most years spring wheat yielded more when following corn and spring grain than when following sorghum, but in some seasons the reverse was true.

The use of barnyard manure gave no appreciable beneficial effect on the yields of the succeeding crop. Rye and field peas plowed under as green manure proved to be more expensive and less profitable than alternate cropping and summer tillage. Nearly all rotations giving a loss were designed to maintain the soil fertility through barnyard manure, a green manure crop, or a grass crop. Corn grown on summer-tilled land, oats grown continuously on spring plowed or on summer-tilled land, and barley on summer-tilled land were also unprofitable. Considering the comparative ineffectiveness of barnyard manure, the most profitable rotation of the series was sorghum, corn,

and spring wheat, giving corn stover a value of \$3 per ton and sorghum a value of \$4 per ton.

Alfalfa and brome grass proved unsuccessful, and it is stated that for the conditions under which these crops were grown they should have been seeded in rows and cultivated. The average yearly yield of sorghum for seven years was 3.1 tons per acre. As a single crop and also in rotations corn ranked above any of the small grain crops in the profit per acre where the stover and grain are both used. Spring wheat ranked next and gave the most profit when following corn in a rotation. Barley gave less profit than spring wheat and oats were usually grown at a loss.

Carrying capacity of grazing ranges in southern Arizona, E. O. WOOTON (U. S. Dept. Agr. Bul. 367 (1916), pp. 40, pls. 10, figs. 5).—The plans and methods of the studies here reported, as well as earlier results secured in the work, have been previously noted (E. S. R., 23, p. 136). This bulletin summarizes the results thus far obtained including those reported in preceding publications.

Regarding the rate of recovery of the ranges it is stated that three years of complete protection gave about three-fourths of complete recovery for the area where crowfoot grama was the dominant grass at levels of about 3,500 to 4,000 ft. with an annual rainfall of from 15 to 18 in. An inclosed pasture of this type of 794 acres stocked with horses and burros at the average rate of 11 head per section recovered somewhat more slowly than the completely protected area beside it, and at the same level, but after 11 years of protection it was not and had not been for two or three years appreciably different in carrying capacity from the completely protected area. Three other areas of 1,065, 1,695, and 1,889 acres, pastured judiciously with approximately all the cattle they could carry, are reported as showing a better productivity than adjacent unprotected grazing land of the same character, and are believed to have materially increased the carrying capacity under the treatment within a period of 11 years. With complete protection the better part of this range recovered rapidly during the first two or three years and approached complete recovery in 10 or 12 years. Heavy stocking with cattle did not prevent but retarded recovery, so that after 11 years the grazed areas were but partially recovered though their carrying capacity had increased at least 30 per cent in that time.

The results of reseeding operations to introduce new species of forage plants or to increase the relative abundance of particular endemic species beyond their natural importance were practically all negative. Scattering the seeds of the best grasses of a region on the denuded areas is recommended wherever the seeds can be had in any quantity at relatively small expense.

Records were made for a series of years to work out an expression representing the average carrying capacity of the whole range reserve. From weights of the dry material collected for nine years on small measured representative areas, the total productivity in pounds of forage per acre was calculated. The yearly averages indicated the rate of improvement, and the average of all records showed an average total annual production of about 1,160 lbs. per acre. The average amount of hay obtained, as based on records covering five years on a total area of 492.5 acres, was 640 lbs. per acre. Three areas of about one acre each cut four years in succession lost in productivity from one-half to three-fourths of what they produced the first year. From the measurements of the small areas the approximate productivity of different forage plant associations was obtained, and from these figures and the areas of each association, the average production of the whole reserve was calculated

at 1,100 lbs. per acre. "Assuming the value of 1,100 lbs. per acre as an average total productivity and 50 per cent of that amount as maintenance capacity for the range, then, if the average animal eats the equivalent of 30 lbs. of dry feed per day he will need 11,000 lbs. in a year, and it will take 10 acres of land to furnish that amount at full productivity, and 20 acres of land at maintenance capacity. Thus we have an average value for carrying capacity equal to 20 acres per head per year, or 32 head per section, for the reserve."

Record was also kept of animal-days' feed consumed for a period of five years on about 16 per cent of the best part of the reserve. The average carrying capacity for 7½ sections, or one-eighth of the whole reserve stocked with cattle was 14.1 acres per head per year. It is stated that this carrying capacity is considerably above that for the whole range. On one of the pastures stocking at the average rate of 58 acres per head per year was considerably below the limit of maintenance capacity, the pasture so stocked being not noticeably different in condition from adjacent land not pastured for 11 years.

Cereal crops in the Panhandle of Texas, J. F. Ross (U. S. Dept. Agr., Farmers' Bul. 738 (1916), pp. 15, figs. 5).—The topography, soil, and climate, including rainfall, humidity, wind, evaporation, and temperature are noted, and farming in the region is discussed. Brief directions are given for the culture of small grains, and the adaptability, importance, yield, quality, varieties, and rates and date of seeding each crop are taken into account. The small-grain crops considered given in the order of their importance as based on average yields are winter wheat, spring oats, winter barley, winter rye, proso, durum spring wheat, common spring wheat, winter spelt, and winter emmer. The grain sorghums, especially varieties of milo maize, Kafir corn, and feterita, are regarded as the most important grain crops for the region.

Fodder grasses of Java, X-XIII, C. A. Backer (Teysmannia, 25 (1914), Nos. 4, pp 209-215, pls. 3; 5-6, pp. 298-317, pl. 1; 9, pp 523-549; 26 (1915), No. 1-2, pp. 86-98, pl. 1).—These articles, which are in continuation of previous work (E. S. R., 31, p. 431), present botanical and cultural notes on Isachne firmula, I. miliacea, I. montana, Panicum miliaceum, and Paspalum muticum. P. miliaceum is discussed at some length, and in addition to its botanical characters attention is given to its culture, feeding value, and chemical composition.

Eleven years' experiments with field carrots on sandy soil at Flahult, H. von Feilitzen (Svenska Mosskulturför. Tidskr., 29 (1915), No. 4-5, pp. 293-317).—Field carrots were grown on sandy soil of low fertility and drought resistance. The carrots followed rye and the soil was fertilized with manure and received in addition an application of superphosphate, potash salts, and nitrate of soda. The yields per hectare for different years were as follows: 1904, 29.9 tons; 1905, 17 tons; 1906, 42.9 tons; 1907, 17.8 tons; 1909, 43.9 tons; 1913, 39.9 tons; 1910, 50.1 tons; and 1914, 39.3 tons.

The variation in yield from year to year was mostly due to the differences in the amount of precipitation. The application of the manure in the fall gave better results than applying it in the spring. White Belgian and Champion were the most promising varieties grown.

Button clover, R. McKee (U. S. Dept. Agr., Farmers' Bul. 730 (1916), pp. 9, figs. 3).—This publication gives a description of button clover, enumerates the climatic, soil, and moisture requirements of the plant, points out its value for hay, pasture, and green manure, and presents directions for its culture. Tabulated data show that button clover at Chico, Cal., for the four years beginning 1908 yielded from 790 to 1,160 lbs. of seed per acre as compared with from 255 to 407 lbs. for toothed bur clover during the three years beginning 1908.

Tests were made in 1915 with seed stored for different lengths of time. Seed grown in 1912 showed a germination of 58 per cent with 2 per cent of hard seed, and seed grown in 1907 germinated 49.5 per cent with 5 per cent of hard seed when four years old, and 29.5 per cent with 7 per cent of hard seed when seven years old. In 1911 a test made with seed grown the preceding year gave a germination of 91 per cent with 4 per cent of hard seed.

Inbreeding in maize, D. F. Jones (Abs. in Science, n. ser., 43 (1916), No. 1104, p. 290).—The author reports that 12 generations of continuous inbreeding in maize confirmed previous conclusions. A reduction in vegetative vigor, rapid at first but gradually slowing down and finally ceasing, was found correlative with the theoretical approach to complete homozygosity. A marked tendency was observed toward complete uniformity within the limits of physiological fluctuation. The reduction in variability was accompanied by a segregation of characters and an isolation of subvarieties differing in their power for development as expressed by the size of the plant and the yield of the grain. It is stated that after continued inbreeding there is an approach to the stability of a naturally inbred race. The constantly segregating characters in the original crossbred race are considered of little value in classification.

A Persian and other forms of emmer, A. Schulz (Ber. Deut. Bot. Gesell., 33 (1915). No. 4, pp. 233-242, pl. 1).—Different forms of emmer are discussed from a historical viewpoint and descriptions are given of some of their botanical characters, especially those of the spike, spikelets, and grains. Among the forms discussed and figured are Triticum dicoccum farrum. T. dicoccum rufum, T. dicoccum var. haussknechtianum, T. dicoccoides var. straussiana, T. dicoccoides var. kotschyana, T. dicoccum tricoccum, T. dicoccum serbicum album, and T. dicoccum farrum album×T. dicoccum serbicum album.

Lespedeza seed, MAYME DWORAK (La. Agr. Col., Ext. Div. Circ. 11 (1916), pp. 11).—The results of purity and germination tests are reported, together with the results of experiments with new and old seed and with different treatments to hasten germination.

Three-year old lespedeza seed failed to germinate and two-year old seed had a very low percentage of germination. Seed with a high percentage of hard seeds in November, 1914, when tested in December, 1915, showed an increase of 11 per cent of germination and a decrease of 34 per cent in the number of hard seeds, but when tested in February, 1916, the germinative value was practically the same as in November, 1914. Corresponding samples of a high percentage of germination and a comparatively low hard seed content in November, 1914, showed practically the same percentage of viable seeds and the same hard seed content when tested in December, 1915, and February, 1916, as the samples mentioned above. Samples tested in February, 1915, had an average percentage of germination of 63.05 and an average percentage of hard seed of 16.07, but when tested a year later they showed an average percentage of germination of only 27.52 and an average percentage of hard seeds of 8.58.

The treatment of lespedeza seed with sulphuric acid, ammonium hydroxid, hydrochloric acid, and hot water, indicated that the use of hot water reduced the germinative power very perceptibly. The application of sulphuric acid so hastened germination that practically all of the viable seeds germinated within three or four days.

Investigation of the injurious effect of lime on the lupine and its prevention, B. CREYDT (Jour. Landw., 63 (1915), No. 2, pp. 125-191, pls. 6).—Studies of this subject by different investigators are briefly reviewed, and results are presented of experiments made to determine whether the lupine is injuriously affected by basic nutritive solutions in general or in particular by those containing lime, and if lime is the active agent whether application of potash can reduce or remove the detrimental effect. Pot experiments were

conducted in which lupines were grown on sand and clay with different lime content and treated with light and heavy applications of carbonate, bisulphate, and chlorid of potash. The data obtained are tabulated and discussed in detail.

The conclusion is reached that the injurious effects of lime on the lupine are due to a specific sensitiveness of the plant toward the substance, and are not the result of a general sensitiveness toward alkalinity. brought together showed that basic as compared with acid soil fertilization had the more favorable effect on the development of the plants; in fact, acid fertilization had a marked injurious influence. The author believes that this specific sensitiveness to lime is due to the solvent action of the lupine and its capacity to take up lime, and that if the lime content of the soil is high the plant makes use of these properties and takes up a large quantity of lime at the expense of the nutrients necessary for its development. It was found in these experiments that by means of applications of carbonate of potash and chlorid of potash the quantity of lime taken up can be reduced and the injurious effect to a certain extent controlled. The investigation further indicated that lime not only influenced the lupine unfavorably but that the particular nodule bacteria were also injuriously affected, suffering a reduction in their activity.

Some recent investigations in sugar beet breeding, F. J. PRITCHARD (Abs. in Science, n. ser., 43 (1916), No. 1102, p. 219).—Data secured in ten years' experiments in sugar beet breeding indicate that differences in the size, total sugar content, and percentage of sugar of individual beet roots show no evidence of inheritance, and that there is no correlation between percentage or quantity of sugar of roots of ordinary sizes and their yield of seed, nor between their yield of seed and the average percentage of sugar in their progeny. Discontinuance of selection for one generation caused no deterioration but some apparent gain in percentage of sugar, and no improvement was obtained in yield or percentage of sugar from continuous selection. Fluctuations in percentage and yield of sugar are regarded as due chiefly to lack of soil uniformity. Real differences between strains and varieties are thus obscured, but may be distinguished by planting each variety or family a large number of times.

Breaking the leaves of the sugar beet as a means of increasing the yield, T. Remy (Bl. Zuckerrübenbau, 22 (1915), No. 17, pp. 189-193).—Plats of Dippe red-crowned sugar beet and Eckendorf original field beet were planted April 22 and on August 7. The lateral leaves of the plants on two of the plats were broken near the stem, but not removed, for the purpose of observing the effect of this treatment on the yield. In comparison with the check plats the sugar beets showed a reduction in yield of 3,213 lbs. and the field beets of 7,229 lbs. per acre.

Making beet seed germination tests, H. Plahn (Bl. Zuckerrübenbau, 22 (1915), No. 16, pp. 177-181).—Several methods of making beet seed germination tests are described and compared and the liability of error inherent in the different plans is pointed out.

The author describes and proposes a method based on the size of the seed bolls and their weight per hundred for which he claims greater accuracy than can be secured with the other methods discussed. The method proposed consists essentially of separating the seed sample into the different sizes of bolls by means of sieves of 2, 3, 4, and 5 mm. mesh, determining what percentage by weight each size forms of the sample, taking from each size five lots of 100 bolls each for the determination of the weight per hundred bolls,

subjecting the first, third, and fifth of these to germination tests, and averaging the results on a percentage basis.

Sugar cane experiments in the Leeward Islands, H. A. TEMPANY ET AL. (Imp. Dept. Agr. West Indics, Sugar-cane Expts. Lecward Isl., 1914-15, pts. 1-2, pp. 76).—These experiments included variety tests and fertilizer trials conducted in Antigua and St. Kitts in 1914-15 and in previous years. The data secured are shown graphically and in tabulated form and are briefly discussed.

In the variety tests conducted in Antigua the leading plant canes and their yields per acre were as follows: B. 6308 produced 3,560 lbs. of sucrose from 22 tons of cane per acre and B. 6450 yielded 3,100 lbs. from 19.3 tons. B. 3412 gave 2,980 lbs. of sucrose per acre and B. 3922, 2,940 lbs. In average production during the past 14 years Sealy Seedling stood first with 6,570 lbs. of sucrose per acre in the juice, B. 208 second with 6,410 lbs., and B. 156 third with 6,290 lbs. The results with ratoon canes the past 13 years placed Sealy Seedling first with 3,720 lbs. of sucrose per acre in the juice, followed by B. 156 with 3,600 lbs., and B. 306 with 3,560 lbs.

In the work with varieties in St. Kitts during the year 1914–15, D. 116 headed the list with a yield of 5,680 lbs. of sucrose per acre in the juice, being followed by B. 376 with 5,510 lbs., and Sealy Seedling with 5,450 lbs. The leading ration canes were B. 1753, yielding 5,300 lbs. of sucrose per acre in the juice. D. 116 yielding 4,940 lbs., B. 1528 yielding 4,760 lbs., and Sealy Seedling 4,610 lbs.

Experiments carried out at Round Hill, Nevis, during this year place Sealy Seedling first in productiveness with a yield of 5,470 lbs. of sucrose per acre in the juice, followed by Λ . 2 with 4,910 lbs., and B. 1528 with 4,510 lbs.

From the results of the fertilizer trials it is concluded that under average conditions the amounts of manurial constituents supplied in 20 tons of barnyard manure per acre applied before the crop of plant cane is established provides sufficient plant food for the production of a crop of plant canes, first rations, and possibly second rations. An additional application of commercial fertilizers, due to the limitation of the moisture supply, is unattended by corresponding increases.

Investigations of the anatomical structure of the leaves of different varieties of spring wheat and its significance in breeding, W. Heuser (Ztschr. Pflanzenzücht., 3 (1915), No. 3, pp. 335-352).—This article is devoted partly to a study of the differences in leaf structure of a number of varieties of spring wheat, and partly to a presentation of different views regarding the significance of the size of the plant cell.

The experimental study of the anatomy of wheat leaves, according to the author, showed that varieties comparatively xerophytic in type are characterized by small size of cell. In this connection attention is called to the fact that Kolkunoff bases selection on the small size of cells in breeding for drought resistance. The author questions the advisability of selecting small cell types of wheat for culture under the conditions obtaining in Germany, but suggests the selection of large-celled and small-celled forms from the wheat varieties commonly grown to compare them with reference to the rate of development and to the morphological and physiological characters that distinguish them.

Marquis wheat, C. R. Ball and J. A. Clark (U. S. Dept. Agr., Farmers' Bul. 732 (1916). pp. 7, figs. 2).—The history and description of Marquis wheat are given, and its value for the subhumid, semiarid, arid, and irrigated sections is discussed. The recommendations given are based largely on the results secured in 13 States in experiments with Marquis wheat by this Department and a number of experiment stations.

For the subhumid section this variety is regarded as comparing very favorably with the principal spring wheats. In the semiarid section it was found that the durum wheats generally outyield the commonly grown spring wheats, including Marquis. The variety is not recommended for the arid sections nor for any district west of the Rocky Mountains either with or without irrigation. It was shown that Marquis is a first-class milling wheat.

The disinfection of seeds, V. M. Archikhovskii (V. Arcichovskij) (Zap. Sta. Isp. Stem. Imp. Bot. Sad. (Ann. Inst. Essais Semences Jard. Imp. Bot. Pierre Grand), 2 (1915), No. 6, pp. 107, pl. 1, figs. 7).—Historical notes on the study of seed disinfection are presented, the author's method of pursuing the work is outlined, and the results secured are reported and discussed. A résumé of the article is given in French and a list of 64 references to literature on the subject is appended.

Different kinds of seeds, including peas, corn, and beans, were treated with solutions of corrosive sublimate, silver nitrate, sulphuric, concentrated hydrochloric, concentrated nitric, chromic, and osmic acids, bromin, chlorin, chlorid of lime, acidulated chlorid of lime, iodin, hydrogen peroxid, formalin, phenol, and soft soap. It is concluded from the results that it is possible to disinfect seeds without destroying their germinative properties, and that chemical substances such as concentrated acids and certain active, especially oxidizing substances such as hydrogen peroxid, chlorin, and bromin, are adapted to the disinfection of seeds. It is stated that in using concentrated acids the organisms on the surface of the seeds are killed before the acids can penetrate into the seeds and destroy their germinability, and that in the case of oxidizing disinfectants the substances absorbed after the seeds are sterilized are not injurious.

Weeds in the poppy fiields of Volhynia and Podolia, K. W. KAMENSKII (KAMENSKY) (Zap. Sta. Isp. Siem Imp. Bot. Sad. (Ann. Samenprüf. Anst. K. Bot. Gart. Peter Grossen), 2 (1914), No. 2, pp. 23).—The results of a study by which the principal species of weeds occurring in the poppy fields of the two governments were determined are reported. Lists of the weeds are given in tabular form, and the frequency of occurrence of the different species is indicated.

The more common species were Amaranthus retroflexus, Chenopodium album, and Setaria glauca. Galeopsis ladanum was also found in both regions, and Oxalis stricta appeared to be characteristic of Volhynia. Seeds of Datura stramonium, Xanthium strumarium, and X. spinosum, weeds growing along the roadsides, were also found in the poppy seed.

HORTICULTURE.

The Australian gardener, revised by F. A. FALKNER (Melbourne: F. H. Brunning Printery, Ltd., 1916, 18. ed., pp. [8]+471, pls. 9, figs. 38).—A manual of information relative to ornamental and vegetable gardening and fruit culture in Victoria, including also a brief section devoted to general farm crops.

Gardening investigations, H. Schmid (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 592-601, fig. 1).—A brief progress report on cultural and breeding investigations with flowers, vegetables, and strawberries conducted at the Wädensweil Station during 1913 and 1914.

The acclimation of plants and their adaptation to soil by means of grafting, J. B. Dental (Rev. Hort. [Paris], 88 (1916), No. 3, pp. 47-49).—The author enumerates a number of plants which he has successfully adapted to different soil conditions by grafting on certain stocks.

A spraying manual (Fayetteville, Ark.: Univ. Ark. Ext. Div., 1916, pp. 16, fig. 1).—This manual contains a monthly working calendar and directions for spraying the more important insect diseases and pests of orchard and small fruits, roses, and vegetables. Directions are also given for preparing various spray mixtures.

How to make hotbeds and cold frames (Harrisburg, Pa.: The Countryside Press, 1915, pp. 74, figs. 21).—In this booklet popular directions are given for the construction and management of hotbeds and cold frames, as well as the smaller types of greenhouses.

How to make a vegetable garden (Harrisburg, Pa.: The Countryside Press, 1915, pp. 73, ftgs. 14).—In addition to directions for planning and planting vegetable gardens, specific directions are given for growing some of the more important vegetables, together with a monthly working calendar and planting table.

Some results in size inheritance, B. H. A. Groth (New Jersey Stas. Bul. 278 (1915), pp. 3-92, pls. 22).—In continuation of previous reports on heredity and correlation of structural characters in tomatoes (E. S. R., 27, p. 742), this bulletin gives the results and deductions from four generations of tomato crosses. Some data are also given on crosses between varieties of Solanum nigrum.

The work done with tomatoes thus far indicates that "the size of cotyledons and first leaves is determined not only by sizes of the respective parental organs, but also by other factors, as for example excess vigor in the F_1 and the size of seed in all generations.

"The range and frequency distribution of size, shape, and number of all characters studied in cotyledons, first leaves, large leaves, and fruits is of the same nature, that is, wider than that of the F_1 or either parent, but like that of a continuous variation, showing in the great majority of cases only a single mode, which agrees closely with the mode of the F_1 unless excess vigor enters as a factor. The dependence of the F_2 frequency distribution on that of the F_1 is much greater than its dependence upon the frequency distributions of the parents. Whether the parents are similar or dissimilar in respect to a certain size character has very little influence upon the F_2 range of sizes as to that character. Instances are given of F_2 frequency distributions which could not have been caused by the Mendelian inheritance of any number of multiple factors.

"The size and shape of the F_1 crosses between \pm round fruits are the geometric means of the parental sizes and shape. In the F_2 the variations in size and shape are caused by the interaction of size and shape factors. When fruits of different shape and size are crossed new shapes and sizes should be expected to appear, some to breed true without the assumption of any multiple factors. The constancy of unit factors of size and shape must be gravely doubted in view of the influence which supposedly absent factors may have upon the development of those present.

"In the discussion the view is expressed that no size character can be due to an absence of a size factor, that an organism can not carry for the same character more than one size factor in a homozygous state or two in a heterozygous state, and that all other sizes appearing in crosses are due to changes in expression induced by the interaction of various factors for size, shape, or other characters. An attempt is made to define a unit factor as a nervous stimulus emanating from the nucleus as part of the centro-epigenetic system in the sense of Rignano. It is suggested that the complexity of the chemical constitution of the nuclear protoplasm, with its multiplicity of electron systems active at all

times and in all cells, is amply sufficient to assume any number of nervous stimuli or unit factors in an organism. It is shown that spontaneous variation (fluctuation), mutation, and the results of selection which run counter to Johannsen's pure line theory might be accounted for if the view advanced is correct.

"The similarity of the F₂ plants of the cross between two varieties of S. nigrum to the mutating species of Œnothera is pointed out."

The transmission of productive and other qualities in the propagation of fruit trees through bud selection, G. T. Powell (West. N. Y. Hort. Soc. Proc., 61 (1916), pp. 85-93).—The author gives the results of some of his own investigations with apples, as well as observations on the work of Shamel with citrus fruits in southern California (E. S. R., 34, p. 639), to show that production and other qualities of fruit are transmitted through buds selected from special trees.

Orchard fertilization, W. S. Blair (Ann. Rpt. Fruit Growers' Assoc. Nova Scotia, 1916, pp. 130-145).—A paper with discussion following, in which the author reviews some of the more important results secured with cover crops, as well as with organic and inorganic manures, in orcharding experiments at the Canada stations.

Pomological investigations, T. ZSCHOKKE (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 586-592).—A progress report on pomological investigations conducted at the Wädensweil Station during the year 1913-14.

The results of an experimental test conducted at the station indicate that, contrary to claims made for it, the placing of tin bands or girdles around young fruit trees has no beneficial effect, either in improving the quantity and quality of the fruit or in throwing the trees into early bearing.

Painting tree wounds, H. G. Cook (Country Gent., 81 (1916), No. 19, p. 988).—In this article the author reports that his experience in painting tree wounds corroborates the results secured at the New York State Experiment Station (E. S. R., 32, p. 835), in as far as peach tree wounds and small wounds on apple trees under 30 years of age are concerned. He is of the opinion, however, that wounds on older apple trees with slower healing capacity will not be sufficiently protected from decay by annual spraying. Such wounds, though perfectly healed on the outside, may be decayed within.

His method of applying carbolineum or creosote oils to the heartwood without injuring the growing sapwood is described. This consists essentially in lightly charging the brush with oil and painting carefully from the heartwood out, leaving a circle unpainted around the outside from § in. to 1 in. in width. In order to stimulate quick healing, the edge of the bark and the sapwood is painted with a liquid wax composed of rosin and beef tallow in solution in alcohol.

Growing fruit for home use in the Great Plains area, H. P. GOULD and O. J. GRACE (U. S. Dept. Agr., Farmers' Bul. 727 (1916), pp. 39, figs. 25).—This bulletin supersedes Circular 51 of the Bureau of Plant Industry (E. S. R., 23, p. 42). It discusses sites for fruit plantations, climatic features of the Great Plains, preparation of the land for planting, selection and care of nursery stock, planting operations, and subsequent management of the orchard. A variety list of orchard and small fruits suggested for planting in the Great Plains area is given.

The problem of finding a profitable market for the products of farms in the State of New York, J. J. Dillon (West. N. Y. Hort. Soc. Proc., 61 (1916), pp. 9-30).—In this paper the author gives a review of the progress made by the New York State Department of Foods and Markets in the disposal of the state fruit crops through the auction system of marketing.

Cultural methods, cover crops, and fertilization in apple orchards, J. P. Stewart (*Rpt. Bd. Agr.* [*N. H.*], 33 (1913-14), pp. 190-208).—In this paper the author reviews some of the more practical results secured from the long-continued orcharding experiments in Pennsylvania (E. S. R., 33, p. 238).

Thirty years in a home orchard, F. J. Heacock (Country Gent., 81 (1916), No. 20, p. 1013).—The author here presents a complete financial history, including costs and returns, of a two-acre apple orchard. The total cost during the period of 30 years was \$1,837.39, and the total net profit \$1,356.01.

Experimental orchard work, 1915, W. S. Blair (Ann. Rpt. Fruit Growers' Assoc. Nova Scotia, 1916, pp. 184-211).—In continuation of previous work (E. S. R., 33, p. 236) the results of cooperative orchard spraying experiments conducted under the direction of the Kentville station in 1915 are summarized.

The following general conclusions are drawn from the investigations as a whole:

Spraying before the leaves open, with special reference to the control of scab, is not likely to give results sufficiently great to pay for its application. Two foliage sprays thoroughly applied, one before blossoming or just after the leaf buds open and the other just before the blossoms open, followed by two applications after blossoming, will give practically clean fruit. The 1.008 specific gravity test strength of lime-sulphur is sufficiently strong to control scab and a greater strength may cause injury to the foliage and fruit.

Lime-sulphur alone is nearly as good a fungicide as lime-sulphur arsenate, but owing to insect injury the arsenate can not be safely omitted. Any of the well-established brands of arsenate appear to give equally good results when used with lime-sulphur. Lime-sulphur is equally as good as Bordeaux for scab control and less liable to russet the fruit. Homemade concentrated and commercial concentrated lime-sulphurs are equally effective for scab control if used at the same specific gravity test. Soluble-sulphur arsenate is not as effective as lime-sulphur arsenate and is liable to cause serious foliage injury. Soluble sulphur is more effective with arsenate of lead than without, this being attributed to the greater adhesiveness of the compound. Barium chlorid proved to be of no practical value for lessening foliage injury when added to soluble-sulphur arsenate. A strength of soluble sulphur generally recommended, 1.5 lbs. to 100 gal. of water, is about as good a fungicide as that of a greater strength.

Protecting the home apple orchard by dusting, D. Reddick and C. R. Crossy (N. Y. State Col. Agr., Cornell Univ. Ext. Bul. 1 (1916), pp. 14, figs. 8).—The authors here give directions for controlling apple diseases and insect pests by the dusting method, with special reference to its use in small orchards.

A successful cold storage for apples, H. F. Hansen (Minn. Hort., 44 (1916), No. 6, pp. 243, 244).—Directions are given for building a cold storage plant suitable for storing apples on the farm.

The principal parasites of the peach, W. W. CHASE (Ga. Bd. Ent. Bul. 43 (1916), pp. 47, pls. 16, figs. 2).—This bulletin gives brief accounts of the life history and methods of control of the more important insect pests and diseases of the peach. An article on the care and management of peach orchards, by R. C. Berckmans (pp. 40-45), is appended.

A promising new pear stock, F. C. Reimer (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 5, pp. 167-172, figs. 2).—In continuation of previous observations relative to the blight resistance of certain pear stocks (E. S. R., 33, pp. 53, 640) the author conducted blight inoculation experiments on trees of a Chinese wild pear (Pyrus calleryana), similar to those previously reported by Compere as being blight resistant (E. S. R., 34, p. 55). These inoculations have shown

that different types of this species, while not absolutely immune to pear blight, are very resistant to this disease. In no case did the blight develop in branches more than 0.5 in. in diameter, whereas check trees of Bartlett, Forelle, *P. pashia*, and French pear seedling inoculated with the same lots of bacteria developed the disease readily and part of them are already dead.

As the result of his studies thus far made with blight resistant pear stocks the author finds that no species are absolutely immune to blight, but that in at least three species the blight has been confined to wood not more than one year old. It is suggested that for very cold regions some of the blight resistant forms of the Chinese sand pear (*P. sinensis*), such as the Japanese pear seedlings and others of this type, will prove most desirable as stocks. For the warmer regions *P. calleryana* and its various subtypes appear sufficiently promising to be thoroughly tested.

Report on new small fruits, W. F. ALLEN (*Trans. Peninsula Hort. Soc.* [Del.], 29 (1916), pp. 83-87).—A report on the cultural value of a number of the newer varieties of strawberries.

Dewberry culture, G. M. Darrow (U. S. Dept. Agr., Farmers' Bul. 728 (1916), pp. 18, figs. 12).—A practical treatise discussing the history of the dewberry, site of a plantation, soils, preparation of the soil, planting, intercrops, cultivation, cover crops, fertilizers, systems of training and pruning, winter protection, harvesting, yields, diseases and insects, propagation, duration of the plantation, pollination, varieties, and hybrids and related forms.

A decade of hybridization among American and Leccean vines, G. CECCARELLI (Staz. Sper. Agr. Ital., 48 (1915), No. 9, pp. 638-648).—The author gives a record of breeding experiments conducted during the period 1904 to 1913, in which different species of American grapes were crossed together as well as with other important hybrids and with native Leccean grapes.

The grape in Ontario, F. M. CLEMENT (Ontario Dept. Agr. Bul. 237 (1916), pp. 48, figs. 29).—A practical treatise on grape growing based largely on commercial practice in Ontario and parts of New York State. Articles on Insects Attacking Grapes, by L. Caesar (pp. 39-44) and Grape Diseases, by J. E. Howitt (pp. 44-48) are also included.

Viticultural investigations, H. Schellenberg (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 572-586).—A progress report on viticultural investigations conducted at the Wädensweil Experiment Station during the years 1913-14.

Among the data reported are the cultural value of a number of varieties of grapes, the adaptation of varieties to different stocks, the results of combating insect pests and diseases, and the yields in fruit and juice secured from different grafted varieties.

Varieties of the avocado, F. O. POPENOE (Altadena, Cal., 1915, pp. 25, pls. 2).—This is a reprint of a paper on this subject, read at the meeting of the Avocado Growers' Association at Los Angeles in 1915. See also previous note (E. S. R., 34, p. 835).

Our present knowledge of citrus fertilization, H. J. Webber (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 5, pp. 161-163).—In this paper the author reviews the results of experiments relative to the fertilization of citrus fruits.

Sicilian citriculture, G. Inzenga, edited by L. Savastano (Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale, 3 (1915), pp. 1-42, pl. 1).—This comprises a monograph on the various species of citrus fruits which was prepared by the author in 1882 and has not been previously published.

Lemon growing in Santa Agata di Militello, Messina, G. FARACI (Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale, 3 (1915), pp. 135-192, figs. 10).—An account of lemon culture in Santa Agata di Militello, discussing soil and cli-

matic conditions, methods of propagation, planting and culture, diseases and insect pests, harvesting, commerce, and cost of production.

Pamburus, a new genus related to Citrus, from India, W. T. SWINGLE (Jour. Wash. Acad. Sci., 6 (1916), No. 11, pp. 335-338).—In this article the author names and describes a new genus, Pamburus, to include certain species related to Citrus which have previously been referred to the genus Atalantia.

Olive culture in the environs of Trapani, D. Poma (Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale, 3 (1915), pp. 111-134).—A survey of the olive industry in the environs of Trapani, conducted with the view of determining the causes of the decline in the industry. The results of the survey indicate in brief that under better methods of culture and care olive growing might well be extended in that region.

Variation in the flowers of the papaya, L. B. Kulkarni (Poona Agr. Col. Reprints No. 4 (1915), pp. 11, pls. 3).—Observations made by the author in the Ganeshkhind Gardens during the years 1910–1913 show that the inflorescence of the male plants of the diecious type of papaya is unstable. At certain times staminate, pistillate, and hermaphrodite flowers have been observed. With the increase of hermaphrodite flowers there is a decrease of staminate flowers and a gradual appearance of pistillate flowers. At other times the pistillate flowers practically disappear, the number of hermaphrodite flowers is decreased, and the number of staminate flowers increased.

The results of these observations together with the results of some experiments in beheading male plants, lead the author to conclude that, contrary to the opinion advanced by Iorns (E. S. R., 20, p. 444), a change in sex does not appear in any way to be connected with the removal or retention of the terminal bud.

Tea culture on the east coast of Sumatra, C. Bernard (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 41 (1915), pp. 58, pls. 14, figs. 5).—An account of the tea industry on the east coast of Sumatra, with reference to its extent, cultural practices, methods of harvesting and preparing the tea, and cost of growing and marketing.

A walnut containing a hazelnut kernel, L. Daniel (Rev. Gén. Bot., 28 (1916), No. 325, pp. 11-14, figs. 12).—The author here describes a case of xenia in which a walnut gathered from a tree adjacent to a hazelnut tree was found to contain a kernel similar to the hazelnut. The seedling from this kernel showed walnut leaves.

Bay oil and the cultivation of the bay tree as a crop plant, H. A. TEMPANY and W. Robson (West Indian Bul., 15 (1915), No. 3, pp. 176-197, pl. 1).—In this paper the author briefly reviews the literature relative to the bay oil and bay rum industries, summarizes the existing information in respect to the culture of bay trees, and gives the principal results of experiments conducted at the Montserrat Station for a number of years in the culture of bay trees and the distillation of bay oil.

The possibility and value of improving the commercial belladonna crop through selection, A. F. Sievers (Amer. Jour. Pharm., 88 (1916), No. 5, pp. 193-215).—This paper is based upon and presents the more important results of the author's selection and breeding experiments with special reference to increasing the alkaloidal content of belladonna plants (E. S. R., 34, p. 237).

Henna, F. Cortesi and G. Tommasi (Ann. Bot. [Rome], 14 (1916), No. 1, pp. 1-27, figs. 6).—A botanical and chemical investigation of the henna plant (Lawsonia alba) is reported.

Report of the committee on plants, C. W. EICHLING, J. RINCK, and J. G. THOMA (*Proc. Ann. Conv. Ry. Gard. Assoc.*, 9 (1915), pp. 24-32).—A descriptive

list is given of trees and shrubs recommended for railway gardening by the committee on plants of the Railway Gardening Association.

Trees and shrubs worth planting for their conspicuously ornamental fruits, E. H. Wilson (Gard. Mag. [N. Y.], 22 (1915), No. 3, pp. 77-80, figs. 11).—A large number of trees and shrubs valuable for their ornamental fruits are described.

Early spring-flowering trees and shrubs, E. H. Wilson (*Gard. Mag.* [N. Y.], 23 (1916), No. 1, pp. 19-23, figs. 12).—Descriptive notes are given on a large number of early flowering trees and shrubs adapted for ornamental planting.

Midseason flowering trees and shrubs, E. H. Wilson (Gard. Mag. [N. Y.], 22 (1915), No. 1, pp. 5-9, figs. 6).—Descriptive notes are given on a large number of midseason flowering trees and shrubs adapted for ornamental planting.

The best of the hardy climbing shrubs, E. H. Wilson (*Gard. Mag.* [N. Y.], 22 (1915), No. 2, pp. 31-35. figs. 12).—Descriptive notes are given on hardy climbing shrubs for ornamental planting.

New Chinese trees and shrubs for the Pacific slope and other favored regions, E. H. Wilson (Gard. Mag. [N. Y.]. 22 (1916), No. 6, pp. 197-200, figs. 8).—Although the trees and shrubs here described are considered to be of particular value for the Pacific slope and the Gulf coast regions, many of the plants are adapted for culture in the South in the presence of sufficient moisture.

In "lilacdom," E. H. Wilson (Gard. Mag. [N. Y.], 23 (1916), No. 3, pp. 153-155, figs. 16).—Descriptive notes are given on various types and varieties of lilacs and their cultivation.

New herbaceous plants from China, E. H. Wilson (Gard. Mag. [N. Y.], 28 (1916), No. 4, pp. 226-229, figs. 18).—Descriptive notes are given on a number of herbaceous introductions from China, including suggestions relative to their cultural requirements and adaptation.

"Consider the lilies," E. H. WILSON (Gard. Mag. [N. Y.], 21 (1915), No. 6, pp. 283-286, figs. 6).—Under this title the author discusses the cultural requirements of various types of lilies as judged by conditions in their native environment.

The story of the modern rose, E. H. WILSON (*Gard. Mag.* [N. Y.], 21 (1915), No. 5, pp. 253-256, figs. 7).—A brief historical sketch of the present day cultivated roses, including a list of parents of the principal garden roses of the nineteenth and twentieth centuries.

House plants, their care and culture, H. FINDLAY (New York and London: D. Appleton & Co., 1916, pp. 325, figs. 125).—In addition to general cultural directions for window and conservatory plants, the control of insects and plant diseases is treated in detail and each plant included is considered with reference to its history, propagation, and culture.

How to make a bulb garden (Harrisburg, Pa.: The Countryside Press, 1915, pp. 73, figs. 22).—This booklet contains concise directions for the planting and care of both spring and summer flowering bulbs.

Our early wild flowers, Harriet L. Keelee (New York: Charles Scribner's Sons, 1916, pp. XXVIII+252, pls. 20, figs. 94).—A popular descriptive study of the herbaceous plants habitually blooming in the Northern States during the months of March, April, and May.

A country flower show, J. H. BURDETT (Country Gent., 81 (1916), No. 20, p. 1045).—In this article the author gives numerous suggestions dealing with the arranging and holding of country flower shows.

FORESTRY.

Announcements concerning forest and shade trees and basket willows recommended for planting in Idaho (*Univ. Idaho*, *Dept. Forestry* [Bul.], 11 (1916), No. 2, pp. 4).—This pamphlet contains a descriptive list of trees recommended for various planting purposes in Idaho, together with announcements dealing with the distribution of trees by the State Department of Forestry.

The forests of Mount Rainier National Park, G. F. Allen (U. S. Dept. Int., Off. Sec. [Pub.], 1916, pp. 33, figs. 26).—A popular account of forest conditions in Mount Rainier National Park, including descriptions of the more important forest species.

Timber of Russia, M. TKATCHENKO (Internat. Engin. Cong., 1915, Sept. 20-25, Adv. Copy, pp. 24).—A paper presented at the International Engineering Congress at San Francisco in 1915, giving an account of forest areas and forest ownership in Russia, and of the forests in the different parts of Russia, with reference to distribution of species, yield, mechanical properties, and commercial uses of the timber, lumbering, and management.

Hybrid trees, W. H. Lamb (Jour. Heredity, 7 (1916), No. 7, pp. 311-319, flgs. 4).—A review of our knowledge relative to natural and artificial hybridization among trees.

British Columbia western larch (Larix occidentalis) (Brit. Columbia Govt., Forest Branch Bul. 16 [1916], pp. 15, figs. 13).—This bulletin describes the western larch (L. occidentalis) with reference to its range, distinguishing characteristics, and the qualities and uses of the wood.

The yellow locust (Robinia pseudacacia), J. J. CRUMLEY (Mo. Bul. Ohio Sta., 1 (1916), No. 5, pp. 149-152, fig. 1).—An account of the yellow locust, with reference to its distribution, habitat, habit of growth, durability of the wood, production and market value, and propagation.

Notes on tapping experiments at Kuala Lumpur.—Third and fourth years' result, F. G. Spring (Agr. Bul. Fed. Malay States, 4 (1916), No. 6, pp. 168-174).—Yield data are given for the third and fourth years on a comparative test of six different systems of tapping rubber. The results secured during the first two years (E. S. R., 29, p. 240) are also included.

Tenth annual report of the commissioner of forestry, made to the general assembly at its January session, 1916, J. B. Mowry (Ann. Rpt. Comr. Forestry, R. I., 10 (1915), pp. 18).—A progress report on forest conditions in Rhode Island, including data relative to forest fires in 1915 and planting and improvement operations by landowners.

Report of the forest officer for the year 1914-15, C. S. ROGERS (*Rpt. Forest Off. Trinidad and Tobago*, 1914-15, pp. 6).—This comprises a brief report relative to the administration and management of the crown forests in Trinidad and Tobago for the year.

Forest Service revenue and organization, T. S. Woolsey, Jr. (Forestry Quart., 14 (1916), No. 2, pp. 188-285).—A study of the organization and policy of the Forest Service of the U. S. Department of Agriculture with special reference to their influence on Forest Service revenues.

The cost of forest improvement systems, P. S. Lovejoy (Forestry Quart., 14 (1916), No. 2, pp. 238-254).—A discussion of the various cost factors entering into the improvement of forest tracts.

Reforesting methods and results of forest planting in New York State, B. H. PAUL (New York Cornell Sta. Bul. 374 (1916), pp. 649-692, figs. 25).—This bulletin presents the results of a study made in 1914 relative to reforesting methods in New York State and the results that may be obtained by planting

forest trees on denuded lands and on worn-out agricultural lands. Thirty-five typical forest plantations in various part of the State were studied with reference to conditions of growth and rate of growth of the trees. The subject matter is presented under the general headings of conditions for establishing a successful forest plantation, results of forest planting, and causes of injury to plantations.

Possibilities of private forest management in New York State, C. H. Guise (New York Cornell Sta. Bul. 375 (1916), pp. 697-746).—This bulletin reports a study of the present condition of private forestry in New York State, discusses the possibilities of future management, and presents data showing what rates of interest under average conditions may be obtained on investments in different classes of timber suitable to management in the State.

Briefly summarized it is concluded that white pine and chestnut are capable of yielding the greatest returns as an investment and are at present the only trees, with the possible exception of red pine, that can be safely grown for profit. The danger of bark disease may eliminate chestnut. Inasmuch as a return of scarcely more than 6 per cent can be realized after from 40 to 50 years from the time the initial investment is started, the possibilities of private forestry, on a small scale at least, are not encouraging.

Operations and costs on Pennsylvania state forests, N. R. McNaughton (Forestry Quart., 14 (1916), No. 2, pp. 236, 237).—A summary to date is given of the work done and operation costs on the Pennsylvania state forests.

The reforestation of the antarctic woods, G. T. Schuster (Bol. Min. Agr. [Buenos Aires], 20 (1916), No. 1-2, pp. 78-102).—An account of the present condition of forest areas in southern Argentina, together with suggestions relative to reforestation of this region. The Oregon pine (Pseudotsuga taxifolia), which is believed to be suitable for this purpose, is considered in detail relative to its botany, characteristics, wood, habitat, and silvicultural requirements.

Seed testing with the Jacobsen germinating apparatus at the Danish Seed Control Station, trans. by J. A. LARSEN (Forestry Quart., 14 (1916), No. 2, pp. 273-276, fig. 1).—A short descriptive account of seed testing practices at the Danish Seed Control Station, including a list of papers related to this question issued by this station.

An improved form of nursery seed-bed frame, D. R. Brewster (Forestry Quart., 14 (1916), No. 2, pp. 183-187, pl. 1).—The author here illustrates and describes a portable, take-down nursery seed-bed frame which has proved to be well adapted for use at the forest experiment stations.

A practical application of Pressler's formula, A. B. RECKNAGEL (Forestry Quart., 14 (1916), No. 2, pp. 260-267).—In this paper the author presents data showing how Pressler's well-known formula may be used in a practical way to determine the current annual increment in mixed selection forest and from this to work out the regulation of the cut. The data given were secured from work done by Cornell University students in the Catskills and Adirondacks during 1914 and 1915.

Business rate of interest and rate made by the forest, F. Roth (Forestry Quart., 14 (1916), No. 2, pp. 255-259).—A brief discussion of the position of forestry as a business investment as compared with other business enterprises.

Summary of costs on a flume and railroad logging operation in northern California, N. C. Brown (*Empire Forester*, 2 (1916), No. 1, pp. 41-44, figs. 2).—Data are given showing the cost of logging and manufacturing lumber on a large tract in northern California. The experience of several years shows that the total logging and manufacturing charges amount to \$13.65 per 1,000 ft. b. m.

Measuring and marketing wood-lot products, W. R. Mattoon and W. B. Barrows (U. S. Dept. Agr., Farmers' Bul. 715 (1916), pp. 48, figs. 13).—The purpose of this publication is to assist wood-lot owners in securing maximum returns from wood-lot products. Consideration is given to the nature and classification of the wood-lot products, units used in the measurement of timber, scaling timber, estimating standing timber, finding the sale value of standing timber, markets and prices, shipping by rail, when and how to sell, the small sawmill, cooperation in marketing, how to prevent the deterioration of cut wood-lot products, and practical helps in marketing.

Lumber markets on the east coast of South America, R. E. Simmons (U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 112 (1916), pp. 121, pls. 15).—This is the first of a series of reports reviewing the lumber markets of South America. The present report deals with the domestic lumber resources of Argentina, Uruguay, and Brazil, and the kinds, dimensions, costs, prices, uses, etc., of imported lumber. Trade methods are discussed, and consideration is also given to special lumber products.

DISEASES OF PLANTS.

Report on the work of the Bureau of Mycology and Phytopathology for 1914, A. Îachevskii (Jaczewski) (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 3, pp. 42-51).—In addition to his previous report (E. S. R., 34, p. 842), the author gives a more detailed account of the work done by the personnel of the bureau in 1914. For the most part the results of plant disease investigations are either published already or prepared for a separate publication in the near future, and for this reason they are only briefly stated in this report.

Experiments to determine control measures for American gooseberry mildew have been continued. Various substances were added to common soda to increase its adhesiveness, but the best results were secured by the use of zinc carbonate and green soap. Barnyard manure increased the amount of the disease, while potash checked it. The author recommends an application in the spring of 30 per cent potash at the rate of about ½ lb. to every 50 sq. ft., followed by a spray consisting of about ½ oz. soda and ¼ oz. green soap in about 3¼ gal. water. This application should be repeated every ten days.

Work on club root of cabbage consisted in testing a variety of soil treatments, such as fall and spring liming and the application of potassium permanganate, calcium chlorid, and soda as preventives of this disease. Fall liming gave the best results, and is considered worthy of recommendation. Combating weeds, destroying diseased plants as soon as they can be noticed with immediate application of lime to the place from which they were removed, collecting and burning all stalks after harvest, and plowing in the fall, accompanied by distribution of lime in furrows at the rate of about 800 to 3,200 lbs. to the acre, are practical suggestions, based on three years' experience.

The work with the so-called "drunk bread" resulted in the isolation from affected grains of two species of Fusarium, F. roseum and F. subulatum, and consequently it appeared possible to outline certain control measures.

A number of other activities of the bureau are briefly reported upon.

Fungus parasites of the higher plants in the region of Kharkov and adjacent provinces, A. A. POTEBNÍA (Kharkov. Oblast. Selsk. Khoz. Opytn. Sta. Fitopatol. Otd., No. 1 (1915), pp. 120, figs. 19).—This publication is the first part of a work which will eventually cover a complete survey of the cryptogamic parasites of plants in the above-named region of the Russian Empire. The present report includes three lower classes of fungi, namely, Schizomycetes (Bacteria), Amœbina (Monadineæ), and Phycomycetes.

Bacterial diseases of plants are said to be of no great economic importance in Russia, and the majority of them are confined to beets. Special attention is given by the author to the Bacterium beticola described by E. F. Smith, which produces galls on Beta vulgaris. The character of this disease as observed on local specimens is slightly different from that described in America by Smith. Crown gall (Bacterium tumefaciens) is present, but the data regarding its prevalence and importance in the province are not complete. An undescribed species of bacterium, named Bacillus petroselini n. sp., is said to cause a leaf spot of Petroselinum sativum. The author made a special study of a bacteriosis of cucumbers, and he concludes that this trouble is identical with one which was previously reported by Burger in Florida (E. S. R., 31, p. 747). A description is given of the causal organism, Bacillus burgeri n. sp.

The group Amæbina (Monadineæ) is given a lengthy discussion. The author describes $Pollinopsis\ beta$ n. g. and sp. and $Amæba\ cucumeris$ n. sp. The first was isolated from beets affected with $Bacterium\ beticola$, and the presence of bacteria appeared to be necessary for the development of the amæba, but the question of the pathogenicity of the latter is considered to be an open one. The second organism was obtained from cucumbers affected with $Bacillus\ burgeri$, and upon examination of local specimens, as well as herbarium specimens from Copenhagen, Denmark, it appeared to be constantly associated with this disease. The author believes that the question of the relation between the bacterium and the amæba is of considerable interest from the phytopathological point of view.

The Phycomycetes give a large number of plant parasites in these provinces.

Complete technical descriptions accompany nearly all parasitic organisms in this book.

[Mycological flora of the region of Sukhum], V. Siemashko (*Mat. Mikol. i Fitopatol. Ross.*, 1 (1915), No. 3, pp. 23-41, figs. 17).—The author gives a list of fungi collected by him in 1913 and 1914 along the Black Sea coast in Transcaucasia.

Along with parasites and saprophytes of more or less general occurrence this list contains six species described as new to science. One of these, Exobasidium eitri, attacks young mandarin fruits, forming on their surfaces a heavy sclerotial layer bearing numerous spores. The disease in general symptoms resembles that which Briosi and Farneti ascribed to an aggregate action of Ovularia eitri and certain other fungi, but the author's fungus is a distinct Basidiomycete. The other five new species, which attack leaves of various plants, are Mycosphærella phaseolorum from Glycine soja, Phaseolus mungo, and Vigna rubra; Sphærulina suchumica from Gossypium herbaceum and Hibiscus esculentus; Cercosporella epimedii from Epimedium pinnatum colchicum; Ramularia trachystemonis from Trachystemon orientalis; and Cercospora guizotiæ from Guizotia oleifera.

[Mycological flora of Province Tersk], N. N. VORONIKHIN (WORONICHIN) (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 3, pp. 7-16).—The author gives a list of fungi which he collected during the summer of 1914 in the regions of Kislovodsk, Pfatigorsk, and Zhelfeznovodsk, Russian Caucasus. This list includes two parasitic species hitherto undescribed, namely, Rhodosticta onobrychidis n. sp., which attacks the leaves of sainfoin (esparcet), and Cercosporella lini n. sp., from Linum nervosum. Leaf spot (Septoria piricola) and rust (Gymnosporangium sabinæ) of pear, fruit rot (Monilia cinerea) and shothole (Clasterosporium carpophilum) of cherry, Microstroma juglandis on leaves of walnut, and Cercospora fraxini and Septoglæum ulmi on leaves of forest trees were the most prevalent of the well-known diseases of economic plants.

The Septoria leaf spot disease of celery or celery blight, G. H. Coons and E. Levin (Michigan Sta. Spec. Bul. 77 (1916), pp. 8, figs. 9; Dutch ed., pp. 8,

figs. 9).—An account is given of the leaf spot of celery due to S. apii, with suggestions for its control. Experiments are reported in which this blight was very successfully controlled by the use of Bordeaux mixture, large increases in merchantable celery being obtained from sprayed plats over those not similarly treated.

Cotton anthracnose, F. M. Rolfs (Oklahoma Sta. Circ. 40 (1916), pp. 3-7).—A description is given of the anthracnose of cotton due to Glomerella gossypii, with suggestions for control measures. These include seed selection, crop rotation, use of old seed, and treatment of seed with hot water and sulphuric acid.

Potato diseases in New Jersey, M. T. Cook and H. C. Lint (*New Jersey Stas. Circ.* 53 (1915), pp. 3-23, figs. 9).—Prepared as a substitute for Circular 33, previously noted (E. S. R., 31, p. 52).

The diseases of the potato, C. R. Orton (*Pennsylvania Sta. Bul. 140* (1916), pp. 37, ftgs. 23).—A description is given of the more prevalent diseases of the potato, with suggestions for their control as far as definite means are known.

A western field rot of the Irish potato tuber caused by Fusarium radicicola, O. A. Pratt (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 9, pp. 297-310, pls. 4).—In a previous publication (E. S. R., 34, p. 246), Carpenter gave an account of laboratory investigations on potato rots due to species of Fusarium. In the present publication the author gives the results of experiments carried out under field conditions in an irrigated region of southern Idaho, where the fungus, F. radicicola, is believed to be well distributed throughout the soils.

It is claimed that *F. radicicola* is the cause of a field black rot of potato tubers in this section, the disease being principally confined to round types of potato, such as Idaho Rural and Pearl. It is also capable of causing a jelly end rot similar to a rot of that character on potatoes of the Burbank group in southern Idaho, though under actual field conditions other factors are considered partly responsible in producing this disease. Neither the black rot nor the jelly end rot makes any progress in storage if the potatoes are kept below 50° F.

As potatoes infected with black rot will bring about an infection of the following crop, it is considered probable that the black rot may be controlled by planting sound potatoes only on lands which have been in other crops for a number of years and by providing good conditions for growth.

Silver scurf of the Irish potato caused by Spondylocladium atrovirens, E. S. Schultz (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 10, pp. 339–350, pls. 4).—The results are given of a study of the silver scurf of the Irish potato, part of the investigation on which was carried on at the University of Wisconsin. The symptoms of the disease, its morphology, histology, etc., are fully described.

While there is considerable range in spore dimensions, the author concludes that there is but one species and not two, as other investigators have claimed. The fungus is negatively heliotropic, withstands a wide range of temperature, its growth being inhibited at 2 to 3° C., but it is not killed at -10° . Its optimum temperature for growth is 21 to 27° , with a maximum of 30° .

The disease may be carried by infected tubers, and under favorable moisture and temperature conditions may spread to other tubers in storage. Disinfecting the seed tubers with corrosive sublimate reduced very materially the percentage of infected tubers, and warm solutions were found to have a more toxic effect on the fungus than cold ones.

Notable contributions on diseases and animal enemies of the sugar beet in 1914, A. Stift (Bl. Zuckerrübenbau, 22 (1915), Nos. 3, pp. 30-32; 5, pp. 52-

56).—Condensed notes are given on selected articles on animal pests and plant diseases of the sugar beet in 1914 in Germany and Austria-Hungary.

Dying of young fruit trees, A. H. Cockayne (Jour. Agr. [New Zeal.], 11 (1915), No. 6, pp. 504-506).—A serious disease already known to affect several varieties of apples, also other fruits, has recently caused heavy loss. It is characterized outwardly by a wilt of buds or young leaves in early spring and inwardly by a browning of the inner bark and cambium. This browning apparently always extends downward with considerable rapidity, being soon followed in typical cases by a souring of the sap and sooner or later by the death of the tree.

Recent work has shown the trouble to be due to a fungus, though such predisposing factors as unfavorable soil and climatic conditions may favor infection. The mycelium is found in the bark, cambium, and medullary rays and vessels, blocking the water-conducting system. The fungal fructifications found exteriorly have not yet been definitely connected with the internal mycelium. The disease is said to resemble somewhat that caused by *Valsa prunastri* in Europe, though certain specimens have shown fruiting bodies of the coral spot fungus (*Nectria cinnabarina*). The organism is thought to be a wound parasite.

Removal of all affected parts or trees is recommended. Regrafting may, it is thought, be practiced with safety.

Some points on the general care of apple orchards, G. P. Stewart (*Proc. State Hort. Assoc. Penn.*, 55 (1914), pp. 89-95, pl. 1).—Discussing measures designed to secure early bearing, control of aphids and red bugs, and immunity to Stippen (or fruit-pit disease), the author submits provisional lists of apple varieties regarded as susceptible in various degrees or as free from the last-named trouble, which is thought to be physiological in its character.

Spot diseases of the apple causing much general confusion, C. Brooks and D. F. Fisher (Better Fruit, 10 (1916), No. 8, pp. 13-15, fig. 1).—The authors, presenting to the Washington State Horticultural Association a progress report on studies designed to lessen the prevailing confusion regarding the nature, appearance, causation, and control of the various apple spot diseases, and discussing the origin and applicability of the names used therefor, state that the names to which preference should be given or to which usage is too firmly attached to be readily changed, are bitter pit, fungus fruit spot, Jonathan spot, corky pit (or drought spotting), and stigmonose.

On bitter pit and the sensitivity of apples to poison, II, A. J. EWART (Proc. Roy. Soc. Victoria, n. ser., 26 (1913), No. 1, pp. 12-44, pls. 3).—Having employed in further investigations the methods described in a previous paper (E. S. R., 27, p. 749), the author claims to have shown that it is possible, by applying poison during the starch stage of development of an apple, to produce artificially every symptom of bitter pit. It is stated that the apples found to be most resistant to poison are also most resistant to bitter pit. Low temperatures increase resistance to poison as well as to bitter pit. The poisoning theory is claimed to be in accordance with all that is known with regard to the sensitivity of the pulp cells toward poisons, to their diminishing resistance with increasing age, and to the changes which take place in the cell, the increased percentage of ash in bitter tissue also pointing in the same direction. It is claimed that it is possible to poison the pulp cells of apples by traces of poison so minute as to be incapable of detection by delicate chemical analysis. The browning of apple pulp is said to be due to the oxidation of tannic acid.

Other chemical and biological considerations are discussed, and a critical examination is made of the views set forth in the reports of McAlpine (E. S. R., 32, p. 751; 33, p. 852).

On bitter pit and sensitivity to poisons, III, A. J. EWART (*Proc. Roy. Soc. Victoria, n. ser., 26* (1913), No. 2, pp. 228-242, pl. 1).—In pursuance of the work above noted, in which the extreme sensitivity of the apple to poisons was made evident, the author has instituted a comparison between these results and those obtained by studies with potatoes, which are also capable of prolonged semidormant existence and which also become discolored by oxidase action when dead, but which, unlike apples, are capable of further growth after being injured.
